RECORD-WRECKERS

... meet the NEW Champ!

Eight months ago Shell announced the first commercial 100 OCTANE aviation gasoline. Today its amazing performance in racing, military and transport aircraft is a matter of record ...

RACING PILOTS have proved that Shell 100 Octane offers an astounding increase in horsepower output. In a recent record-breaking performance Shell 100 Octane gasoline located speed approximately 31 m.p.h. above the maximum possible with 87 Octane.

TO AIRLINE OPERATORS, Shell 100 Octane brings greater safety. An example: A transport with a range of 1400 miles, powered by two 450 h.p. engines. By changing from 87 Octane to Shell 100 Octane, the fuel load can be reduced approximately 480 lbs. With only minor modifications in present equipment.

TO ENGINE DESIGNERS, Shell 100 Octane opens the door to higher compression ratios and higher injection pressures ... higher engines ... for greater horsepower output per cubic inch displacement.

SHELL 100 OCTANE, which complies rigidly with all leading

Tests Prove Shell 100 Octane Gasoline Makes It Possible To:

- Increase top speed 5 to 10%
- Boost horsepower output up to 25%
- Reduce cylinder head temperatures 15 to 20%
- Cut fuel consumption 10 to 20%

specifications for aviation gasoline, contains no more tetraethyl lead than do regular 87 Octane gasolines!

Thus you gain the highest octane performance and at the same time avoid the increased engine operating and overhaul costs resulting from "over-doped" gasolines.

Fuel data service for operators

Members of the aviation industry are invited to write for recommendations on any specific fuel problem—and for information on Shell's new line of improved aviation fuels.

Address: Shell Aviation Department, Shell Oil Company, San Francisco, or Shell Petroleum Corporation, St. Louis; or Shell Eastern Petroleum Products, Inc., New York.

SHELL 100 OCTANE AVIATION GASOLINE

Backed by 10 years of operating experience
A RECORD UNAPPROACHED BY ANY OTHER AIRCRAFT ENGINE

Five thousand Wright Cyclone engines have been sold during the past 10 years—1928 to the first six months of 1938. No other aircraft engine of similar horsepower has been so widely used—or has achieved such a proven record of dependability in all types of military and commercial service. Cyclone dependability is based on 10 years of operating experience under the most demanding service conditions of U. S. Army and U. S. Navy service duty and air transport operations throughout the world.

The new Series "GP" 1000 H.P. Wright Cyclone is installed in all of the latest intercontinental Douglas Army Bombers, four-engined Boeing Army Bombers, Martin Bombers, Curtiss four-engined Army Attacks, Grumman Navy Fighters, North American Army Observation and many other advanced types of military planes now being built.

For the U. S. Army Air Corps and the U. S. Navy Department.

In the commercial field, Wright Cyclones power all of the high-speed Douglas DC-2 and Douglas Super Transports now in service on American Airlines, Eastern Air Lines, and Transcontinental and Western Air. In foreign fields, Cyclones also power Douglas transports on Pan American Airways System, K.L.M. (Royal Dutch Airlines), K.N.L.M. (Dutch East Indies), Swiss Air Lines, China National Airways, Japan Air Transport, Holiday's Airways, Ltd. (Australia) and many other airlines throughout the world.

During 1936 commercial air transport operations with Wright Cyclone-powered equipment a total of fifty million miles equal to 2800 trips around the world at the Equator. This record is unapproached by any other aircraft engine now in service on airlines throughout the world.

By Capt. Rudolph John

Director, Luftflotte

Deutschland über dem Nord Atlantik

GERMANY'S interest in trans-Atlantic flying which culminated in the survey flights of the two Dornier flying boats *Zepher* and *Arctur* late this summer dates back many years. In 1929 Deutsche Luftflotte A.G. inaugurated a ship to shore service for mail in conjunction with the North German Lloyd line ships *Bremen* and *Europa*. No trans-Atlantic service was undertaken at that time, but the plan was to save on mail schedules by outstopping planes from the steamer when about 600 miles off the coast when approaching the United States or Great Britain. Single-engine two-seat Junkers airplanes with a crew of two pilots were used. The average mileage in time amounted to about 50 hours on mail deliveries. Accelerated mail service of this type was carried on regularly for eight years during the summer months only.

The experience with the mail service proved so satisfactory, and so much was learned about outstopping that when flight operations across the South Atlantic were being studied, the use of a catapult for launching the larger flying boats was considered the most practical device to adopt. The *Hindenburg* (who had done much of the early work with catapults) designed equipment suitable for launching flying boats up to a total gross weight of 15 tons.

After exhaustive tests ashore it was decided to install

the equipment on board a ship. A small freighter, the *Wesphalen*, was secured and her upper works rebuilt to accommodate a catapult forward (of the same type to be described later for the *Schleswig-Holstein*) and a crane for hoisting flying boats aboard was installed aft. Most novel part of the equipment was a large canvas apron which could be trailed astern and which made possible a sort of ramp onto which flying boats could be towed before being hoisted on board. Without the apron it would be impractical to try to secure the boat to the crane in any sort of way. The apron established a reasonably fixed relationship between the crane and the flying boat and enabled it to be taken on board without damage.

In these days the range of the Dornier Waals which were being used for the service was not great enough to fly the whole stretch across the South Atlantic, and the *Wesphalen* was stationed halfway between Baltimore and

By Willy Ley

NEW problems connected with modern aviation are so frequently discussed, so often misunderstood, misinterpreted and misstated as rocket propulsion.

Though the principle of reaction has been applied in various forms since the days of rockets, Greece, and though powder rockets were known and so we see that modern aviation (the oldest career known) is a Chinese invention relating to the birth of Kung-Fu in 1322 A.D., scientific rocket research is of quite recent origin. Rocketry is still in its infancy.

The first treatise that clearly indicates the theoretical possibility of reaching the limits of our atmosphere by means of rockets were published in 1765 by the Russian scientist Konstantin Eduardovich Zakharenko. In 1919 followed the publication of Dr. Robert H. Goddard's book, "A Method of Reaching Extreme Altitudes" (Smithsonian Misc. Coll. vol. 71, No. 2) and in 1929 Professor Hermann

Oberth's "Die Rakete zu den Planetenräumen".

The basic principle of rocket behavior is established by Newton's Third Law of Motion, "Translated freely it says: 'Reaction is equal but opposite to action, or the action of two bodies has equal (in power) but in opposite directions.'" Or, in mathematical symbols, $MV = -m\dot{v}$, where M and m are the masses involved, V and v are the velocities.

The action of a rocket, therefore, is independent of the pressure and/or nature of the surrounding medium. Neither the density nor the pressure or absence of air can be of any influence on the fact that a rocket will move. They can only change the flight performance and (consequently) the efficiency. Though this may be misleadingly stated it may be difficult for newcomers to the problem of rocket propulsion to visualize. Actual experiments have shown that the rocket does move in a vacuum. The following example may

help to make the procedure understood. Imagine a rock in a space where there is neither air nor any other gravity to overcome. Imagine further that the rock is divided into two parts by an explosion—or by the action of springs—both parts will fly in opposite directions. Assume that both parts are of equal weight (mass), therefore the velocities will be equal. The two total of velocities being $2v$, each part has the velocity $v/2$. Every part one of the two parts, explode the other one into two equal parts with the same force. One part will then have the velocity $v/2$ plus $v/2$ or v while the other part has the velocity $v/2$ minus $v/2$ or zero.

The remaining mass after the second explosion will be $1/4$ of the original mass. Thus, in order to give the velocity v to one part of an assumed mass it is necessary to sacrifice $3/4$ of the mass.

Generally speaking, the increase in speed for the remaining mass is v/n , n being the number of explosions. The

AVIATION
November, 1938

loss of mass after each explosion is $n/n+1$ of the original mass. The remaining mass is $n/n+1$.

After an explosion the remaining mass

$$m_1 = \frac{m - \Delta m}{n+1}$$

The two examples show that more explosions with smaller particles give better results, the optimum will obviously be an infinite number of explosions expelling infinitely small particles. The formula thus becomes $(m - 1/n)$, its result is 0.008 or $\frac{1}{125}$.

$1/125$ of 2838 kg —the loss of Napier's "cannon" experiment. Using the factor n we can simplify the formula to

$$m_1 = m_0 \left(\frac{n}{n+1} \right)^n$$

Actually this formula was derived from the differential equation

$$m \frac{dv}{dt} = -v \frac{dm}{dt}$$

which is usually called the "basic formula of rocket propulsion." In all these formulas v designates the speed of the rocket while v stands for the exhaust speed. It is obvious that v is of greater importance than the loss of mass and generally (if the resistance of the air does not become prohibitive) a dud with a higher v will be superior to a dud with a lower v . For this reason scientific rocket experiments have abandoned powder for a fuel completely and now work only with liquid fuels which, in addition to higher exhaust speeds, are easier to handle and to control.

Furthermore, there is no real fuel that is an explosive in itself. So-called "oxygen-carriers" have to be added to make the fuel combustible. The "oxygen-carriers" are usually pure oxygen which is added to the fuel immediately before combustion.

It is of no consequence whether oxygen is carried in the liquid state or as a gas. Experiments have been carried out with vapor, with the result: fluids liquid oxygen in the more practice as it does not require the heavy tanks that must be used for the highly com-

pressed gaseous form. It is true that liquid oxygen, because of its extremely low temperature, is not very easy to handle. With a little practical experience, however, it is not more difficult to handle than liquid water.

Of the many fuels that were investigated theoretically and tried out experimentally three proved to be very effective and convenient: liquid methane (CH_4), alcohol and gasoline. Which will be used for a special task depends on other circumstances, for example, on the amount of oxygen that can be carried, and on the available space for the tanks at the disposal of the experimenter. The amount of oxygen necessary to achieve complete combustion varies with the fuel, as will be seen from the combustion equation of the three fuels mentioned.

It might be advisable in some cases to select alcohol in spite of its lower caloric content because it needs less oxygen for combustion. In other cases gasoline might be superior in spite of its larger weight, as liquid oxygen will be carried. For practical purposes it will actually be necessary to use liquid methane, which might be considered only for special scientific work.

Both propellants are placed in separate tanks, usually of aluminum alloy. Normally the oxygen tank must be best insulated to prevent the liquid oxygen from building up pressure of its own volition. In general, the less heat that with non-insulated oxygen tanks, diffusing the pressure that automatically develops in the tank to feed the liquid into the rocket motor.

The term "rocket motor" which has been coined by the German experimenters must not be misunderstood as something as internal combustion engine with some kind of rocket action. Actually the term rocket motor designates a device for continuous explosion-like combustion of liquid fuels in the presence of liquid oxygen. A rocket motor consists essentially of only two parts, the combustion chamber and the exhaust nozzle. There are no moving parts in a rocket motor nor in a well-constructed rocket.

In order to show how a rocket motor works and how a rocket flight is made it will be best to describe one type of liquid fuel rocket of extremely simple construction that has made several successful flights. The example chosen is one which we developed and built in Göttingen which we called "Raketen".

The Raketen consisted of two long slender barrel tubes of "Electron", a magnesium alloy of great tensile strength and light weight. Between the two tubes a small metal mesh made of aluminum alloy was placed

The tanks were connected in order to have some fuel at a discharge of compressed nitrogen that was to force the fuels into the combustion chamber.

The combustion chamber and the nozzle of the rocket motor were mounted by a water jacket for cooling purposes. The blast of the rocket motor does not spread if the nozzle design is correct, therefore there was no danger of the very hot flame reaching the tanks. It proved the pressure and a little diaphragm mechanism for releasing the parachute at the right moment near the apex of the flight. In proving stand tests (ground tests) where the rocket motor was used to a device measuring and recording its thrust it had been found that the parachute container could be placed on the path of the rocket for a certain time at a certain distance without being harmed easily.

The assembly of rocket motor, two tanks, parachute container and frame represented the Raketen, which was larger than a small rocket and had been tested successfully. (Before firing pressure is applied on the tanks amounting to approximately 300 lb per sq. in.) It was known, unfortunately as well as experimentally, how many pounds the rocket motor would burn with the quantity of fuel in the tanks. It was easily computed how many seconds the Raketen would sustain two or several jumps after the rocket motor had ceased firing. The total time (18 sec in our particular case) was the time that had to elapse between the take off and the explosion of the parachute. The parachute started working automatically when the rocket left its launching cradle. When the calculated time has elapsed the rocket comes about to a standstill and the releasing mechanism ejects the 18 lb parachute which brings it safely back to earth.

Since it is impossible to express the power of a rocket motor in ordinary scientific terms, we simply have to invent a new type of description. The thrust of the rocket motor suggested itself for this purpose, but it is insufficient if it stands alone. Therefore the fuel consumption was added according to a key. For example, in the proving stand rocket motor of the type used in the Raketen flights delivered a thrust of approximately 30 lb with a fuel consumption of 150 g per sec. The description became therefore "30/150". Since there is a definite relation between fuel consumption, thrust and exhaust velocity ($P = v \cdot \dot{m}$, which is the designation for power) we calculate the approximate exhaust velocity v .

Thrust diagram of a liquid fuel rocket motor built by the German Rocket Society.

This type of rocket motor was the simplest built at the proving ground (the so-called *Poltergeist*) at the German Rocket Society. The burning time was made to vary between 30 and 90 sec, which is about the time rocket motors have to burn in altitude shots. The next type was called "20/60", and the largest type tested was "15/300". Consuming approximately 1.7 kilograms fuel per second it delivered a thrust of approximately 200 kilograms for periods varying between 20 and 25 seconds. These rocket motors made possible the construction of airplanes weighing 120 kg.

The most appropriate application for rocket motors are for altitude rockets to carry instruments into layers of the atmosphere that cannot be reached by other means. Although these so-called "aerological rockets" may lead to anti-aircraft rockets it is doubtful whether rocket motors will ever be able to replace the internal combustion engine for ordinary aircraft. A number of nations are busy trying to overcome the main obstacle, the low efficiency at low speeds.

The efficiency of a rocket—or rather its overall efficiency—is the product of the "motor" (E_m) and "motor" (E_{tm}) efficiencies, usually called the thermal efficiency (of the rocket motor) and the ballistic efficiency (of the rocket itself).

The "motor" efficiency

$$\eta_m = \frac{m v^2}{m_0 v_0^2} \left(\frac{v}{v_0} \right)^2$$

It is under any condition substantially the same for a given motor, motor burning a given amount of given fuel. The "motor" or ballistic efficiency, however, depends mainly upon the velocity of the rocket. Following Dr. Eugen Sänger of Vienna

$$\eta_{tm} = \frac{m v^2}{m_0 v_0^2} \left(\frac{v}{v_0} \right)^2$$

$$\eta_{tm} = \frac{2v}{v_0 + v}$$

It is disposed whether this formula is valid or not, but up to 0.9 it is the formula certainly holds good. It is obvious that velocities approaching the exhaust speeds of various fuels (ranging from 1800 in per sec. to close to 4800 in. per sec.) cannot be exceeded except in vertical rocket flights.

A special case exists, however, which offers conditions under which a short and powerful push exerted by rocket motors may prove very valuable in spite of low efficiency. This special case is the take-off of airplanes (in general and the catapulting of airplanes in particular). It is well known that the take-off (especially of heavily loaded airplanes) often meets with considerable difficulties and that a very

long "run" is required until flying speed is attained. Other airplanes often face the same difficulties especially when overloaded and when taking off from smaller airports. If it were possible to furnish additional power only for the few seconds of the take-off many problems of modern aviation would become much easier to solve.

A rocket motor suggests itself for this purpose. An airplane engine with a thrust of 1800 kilograms or 2,200 pounds is a rather big affair, but five smaller rockets of the type "15/300" could furnish about 1500 kilograms for 25 seconds. They would see up

1 — Oxygen tanks.
2 — Fuel tanks.
3 — Nozzle, where combustion starts.
4 — View of the four external rockets.
Rocket motor for liquid fuel developed by Professor Hermann Görtz.

One of the large "Vehicular" of the German Rocket Society. The rocket was up to 15 kilograms, the altitude reached amounted over 1,000 ft.

AVIATION
November, 1939

170 kilograms of fuel, 40 kg. of which would be gasoline. The five rocket motors (of exactly the type that has been constructed and tested) would weigh approximately 27 kilograms, while a specially constructed 1500 kg. rocket motor would probably weigh 40 per cent less.

These figures sound rather high but the example has purposely been carried to the extreme to show that even then it might still be taken into consideration. Actually, an additional thrust of 2200 lb. will greatly exceed the demand, although without compensation it will be very hard to tell how much additional rocket thrust will be most advisable and most convenient for a given type of aircraft. Actually the method has been tried in early as 1929 by the Junkers plant at Dessau, Germany. As far as we know the experiments were made with batteries of the largest type of powder rockets known. The airplane used was a Junkers hydroplane of the "Brennstoff" type, weighing a little over two tons. The result was officially reported as "very satisfactory and encouraging" but no data were published.

The advantages of the "launching rocket" are numerous and rather important. It will facilitate the take-off of airplanes especially from limited space. Furthermore it will obviate the need for too powerful motors in certain types of aircraft and reduce fuel consumption. It will enable the pilots of other airplanes to take off without help. It is conceivable that launching rockets might replace catapults in general, which would be a very considerable gain in capital expenditure. In addition to all this the pilot would "carry his catapult with him" and would be in a position to take off again after a possible forced landing from a limited ground.

The disadvantages of the launching rocket is its own dead weight (between 20 and 40 lb.) and the dead weight of the oxygen containers. The airplane itself will be used up during the take-off so that there is no need to take it into consideration.

If we assume that a certain type of aircraft demands an additional thrust of 200 kg. for 30 sec. the additional weight would be 6 kg. for the rocket motor (this will probably be reduced later to about 4.5 kg.), 36 kg. for the fuel. Of the latter there are 8 kg. of gasoline, so that 28 kg. of oxygen would have to be carried. In the required state 26 kg. of oxygen are approximately 35 liters. The container would weigh around 15 kg., so that the additional weight would be 30-32 kg. This is by no means prohibitive.

AVIATION
November, 1939

... So Must Sales

When a company sells more airplanes than anyone else in a year and then contracts for more engines than have ever been installed in any previous commercial order, it is time we looked into their sales methods. Here the sales manager tells how he did it

TWO simple words express the ultimate goal of all merchandising effort. They are "continuous activity." It doesn't matter whether you are selling fish or food or furniture. The clock keeps going round and around and with it goes the outreach. And out over the most obscure sides of every salesman's brain ever laid or etched into as its flight.

Like going to Heaven, there are many, many recommended methods of achieving continuous activity in a sales force. We have tried most of them during our five years of selling Cals and out of the long experimentation, and a thorough study of merchandising methods in many fields, have evolved the present plan. Tomorrow we will explain a brand new field of merchandising we approached the problem with eyes wide and related to achieve any

theory with a fixed determination to make it work. Rather, we felt our way along and made modifications in our methods whenever the occasion demanded them. Our progress has led us through most of the mercurial steps from small volume history sales to a cloud territory selling organization involving all 48 states and some 33 foreign countries. Our present system involves distributors, dealers, factory representatives, and export agents. But let us go back to examine the beginnings.

First sales were made by history representatives and advertising. We soon learned that planes were not sold

by ads alone. The advertising campaign had to be supplemented by demonstration and personal sales effort. That it was to a lesser extent today than it was in the beginning. But it is still true.

Next we stepped into the field of semi-territory dealerships which aimed to be the last way to close the greatest number of sales. But the majority of our purchasers then were operators who bought ships for instruction and other non-scheduled activities. They wanted five or more states of closed territory. The Mississippi Valley was about the right size. Pilot Jones of Gallopville, Ohio, gave us a chance to be around Springfield and he hoped to make the sale. In the meantime and sooner he wanted three in his territory.

By H. W. Weld
Sales Manager
Taylor Aircraft Company

Obviously large closed territories would not work for a while we treat open territories. Dealers were alerted about areas only in their home cities and states. This ambiguous advice was intended to be of opinion. It was sufficient and useful. For example, a severe dealer or agent would spend a lot of time bringing a prospect up to the purchasing stage. First, doing of this sale might be delayed by financial problems of the prospect. Another dealer happens in at the right moment and wins the deal. The first dealer is discouraged. The total sales of both dealers might have been said on many more prospects.

To remedy these defects we turned gradually to the closed territory system of distributors. By offering all possible effort to avoid dealers in closed sales in their territories. Factory representatives called on dealers to assure us through lists. Prospects lists received from advertising were immediately forwarded to dealers. New sales in advertising and selling were reduced to zero. And we helped them handle "underbid" and with the problems of negotiation and distribution of sales.

Sales increased considerably under this plan. Prospective demonstrations were provided for prospects. Flight instruction, maintenance service, and assistance in delivery were available to new purchasers. Our vision of a huge organization, inefficiently managed from a home office and draining our resources, began to fade. The new perspective was positive. The territories of geographic dealers showed a high percentage of sales to population and per capita while other areas showed little or no activity. In many instances we found a dead territory could be revived through instruction and encouragement of the dealer by a factory representative. When a dealer showed lack of interest or poor sales ability our factory men could replace him.

This experience revealed two facts: (a) local dealers required the assistance of outside ones in a great extent, (b) many of our overseas dealers showed the ability to work large areas. This led to the division of the country into distributorships headed by dealers of demonstrated ability. The new arrangement also solved the problem of delivery, service, trade-in aid, before the days of true payments the handling of a few hundred miles.

Under this system a distributorship could attract sufficient return on investment capital and a dealership might well be a substantial asset in a local airport or flying school whose operation could not derive its entire flow in sales work or employ customers. In spite of the rapid growth of the low

priced plane field, we have found that Cub sales in a small territory cannot yet be depended upon as a sole source of revenue for an individual. But the reasons of distributors and dealers to the company cannot be rapidly fixed for long periods of time.

Distributor contracts

Our distributor contracts, reproduced herewith, are drawn as simply as possible. We require that a distributor purchase a given number of Cubs during a twelve month period. If he is unable to fulfill this requirement in any given month, he is privileged to pay a deposit on his quota and take delivery later. The company, in turn, pays the distributor an endorsement on all sales in his territory. As a possible aid to security, this endorsement, or distributor commission, is based on the quantity of "Cubs" sold and increases up to a certain volume of business in proportion of the quota specified in the distributor's contract.

In case a distributor is unable to fulfill his contract, he is "debarred" to a dealership without extensive financial loss to himself. While the company may lose some sales through basic quota operations in such cases, it is immediately able to appoint another distributor for the area and the company or individual who failed to make good as a distributor remains on record to the company as a dealer.

We require that the distributor maintain a demonstrable and at least one Cub in a showroom or hangar. This insures his ability to display an attractively new plane to prospects and

assist in making immediate or prompt delivery to purchasers. The distributor must devote his entire time to the business of selling Cubs or employ a full time salesman for this work. He must have his territory at least four times a year, assist dealers in closing and building sales, relay the prospect list secured through our national advertising to the proper dealer, and otherwise arrange to connect such prospects.

Dealers

Dealers are appointed to handle a certain percentage of population but do not have closed territories. In large cities, for instance, several dealerships are feasible at present and, in the market branches, additional dealers may be possible. However, as we are considering future possibilities of such scope that each dealer will eventually market more Cubs than our distributor can do at present.

We consider territory as the immediate vicinity of the airport, or dealer's base, in his selling area and discontinue a duplication of effort. Yet it is possible to prevent a prospect living near our airport from purchasing from a former licensee or friend located at another airport. As present our dealers are authorized to sell anywhere in the territory of their distributor. The man who does the sale gets the dealer's commission. That arrangement seems to be preferable to a freely drawn closed territory plan.

A man recently commented that we have our system wrong. A prospect whose residence is in Birmingham, Georgia, spent some time in Iowa

This simple contract covers all distributor relations with the company.

While there he took local restrictions from a Cub dealer and became interested in purchasing. A little later his prospect purchased a Cub from a dealer in Florida. The dealer in Florida secured the dealer's commission on the sale. The distributor in Georgia secured the endorsement on the sale and the Iowa dealer who failed to close the sale, had to charge his work to good-will. This is as clear a plan as we can conceive.

Our distributor and dealer contracts might be shown to great length to cover the many angles of Cub distribution. But we cover the fundamental items in the simpler agreement and the main terms of our representatives handle the cases. We want "continuous activity" regardless of the number of weeks used to sell a Cub. In return, we furnish dealers and distributors every assistance possible to make their merchandising a profitable undertaking. It is our sincere desire to have each dealer earn a commission on every Cub sold.

In our distributor contracts, we reserve the right to cancel if sales are

made outside the allotted area. This applies to dealer as well as distributor. In case of violation, we are able to transfer the proper distributor and charge the amount of the commission back to the violating dealer or distributor. So far, our only action in this respect has been due to mistakes.

From the foregoing, it is apparent that the "dist" among our dealers is automatically always themselves. Other dealers get the orders and the commissions. Dealers who usually undertake a distributorship are, in the course of time, returned to their former status. This also means a fair proportion in all concerned.

Delivery, used planes, financing

We now have 35 distributors in the United States. In one of our largest problems, that of delivering Cubs to purchasers at low cost, the aid of these distributors is invaluable.

Two examples in the far west, Aircraft Associates of Long Beach, Calif., and Air Wholesalers of Portland, Oregon, have kept trailers which carry

two Cubs on the roads continuously for long periods of time this year. On several occasions two or three planes, either purchasers or dealers, have ridden to the factory on these trailers and flown planes west while two rode the trailer. We also have two trailers of our own which are constantly in use ferrying Cubs. We have shipped by rail and seaman and many Cubs have been flown to purchasers. Although most of delivery by distributor cooperation may not be greatly reduced, the assistance of distributors in the details of delivery is valuable to us, and is far more satisfactory to the purchaser than anything we could work out ourselves.

Before the advent of the distributor system, we were forced to devote considerable effort to handling and disposing of trade-in or used airplanes. Now our trailers are handled entirely by the distributor and dealer. We do not allow a discount on deals where a used airplane is accepted by the company in partial payment. The dealers and distributors are in the field where the prospects are likely and this arrangement is by far the most economical means of handling used planes. Frequently, the dealers have buyers waiting before accepting a trade-in.

In the foregoing text, the dealers and distributors are on the ground and easily able to ascertain the soundness of a prospective purchaser's background. They are required to disclose the notes and contracts on deferred payment sales. After disclosure of several hundred Cubs on the finance plan, we have experienced practically no losses, either to the Taylor Company, the finance companies, or any of the dealers.

The consumer pays

The underlying aim of our company is to produce a good plane at the lowest possible price. In his five years of financing and managing the company, the efforts of Mr. William T. More have been continually directed in reducing overhead. The finished delivery a month continued to produce two planes a 250 a plane. On the 30 planes which could be handled with the same cost the company would be reduced to \$40 per plane, or a saving of \$40 to the purchaser.

The same principle applies in selling Cubs. Whatever is expended in merchandising the plane must be added to the total price. Hence our effort to build a selling organization that will dispose of 35 Cubs at the lowest cost of making has a direct and important bearing on prospective firms, with limited financial means.

Two Cubs can ride so cheaply as one in this trailer outfit.

The second fundamental point in air policy is that it should place a limit on governmental responsibility. It should prevent the man on the street, the passenger, the purchaser of a plane (as it should not protect the individual against himself). As a result we have then seen many complaints that the Air Commerce Bureau was neglecting its job by protecting them from flying. There is a distinction, however, between the regulation of public safety and the protection of an individual against himself. An ATC plane should have a certificate of performance and there should be a "flying checklist" and "time of operation" certificate.

The third point in air policy foundation is concerned with transport. Its needs are as follows:

1.—There is needed a more orderly and automatic system of scheduling and to operators. It is a belief in Washington that cooperative bidding is the only way of having contracts. This system has twice broken down in most recent awards. Only recently the ICC has been given the right to adjust rates.

2.—Customs cooperation should be perpetuated to serve aviation. Routes should be paid halfway for what they carry.

3.—It is felt that services must be extended where traffic is slight, the approximate nature of the residual has should be recognized and direct aid should be given to support it.

4.—Case control should be exercised over the extension of air transport in all phases.

5.—Good operating practices should be promoted. Routes at profit are not clearly defined in the air mail act. The present system approaches that cost-plus method which always places a burden on waste.

6.—Emergency operation should be open to competition, with control vested in some responsible agency. The speaker expressed his feeling toward a special commission but said the

ICC was doing a good job and there are some advantages in this arrangement.

7.—Subsidies to air mail operators should be self-canceling.

Radio in every plane

Among the speakers at the "Federal and State" round table was J. Carroll Coss, of the Air Commerce Bureau, who said in part, "Radio as a rule are considered to be for the convenience of the pilot and they are especially so when they are not thoroughly understood and the desired objectives appreciated. When our first bulletin regarding air traffic control of non-scheduled commercial flyers was published, it was particularly in the same category as the Volstead Act—to regulate it, it could not be enforced. The Bureau was not given the cooperation it desired due largely to misunderstanding on the part of the pilots affected. But now we have called several conferences of representatives of all phases of non-scheduled aviation flying and discussed their matter in detail with them and then revisited the subject in the form of a regulation, we are getting splendid cooperation from all parties who manifested our attitude in setting up traffic control systems governing non-scheduled aviation flying."

In the discussions that followed Coss said that it now appears that at some future time the Bureau will probably be forced to require at least a radio receiver on every plane flying along any designated air route. It wants to operate on and from congested air line terminal airports. It was later emphasized by Theodore Edgar Yield that this regulation would apply only if the pilot was to operate in or out of a terminal airport.

This question was discussed at all of the speaker conference last year of the Airport Commission, *Aeronautical Cham-*

AVIATION
November, 1935

ber of Consumer Set Aviation, July 1934, pp. 35-36.

As Jerome Leffner contributed the thought that there should be a steady radio power plant at each traffic control station; when neighboring secondary airports are used, wire control should be substituted for line control as in Germany, radio equipment should not be piled up in towers in such a way as to destroy vision; towers should be air conditioned and independently qualified; stations of operation should be carefully considered, and ships should not be permitted to turn up under control towers.

Airports can be divided as regional or national and the dividing line between federal and state supervision should be at the point where the airplane wheels touch the ground in the opinion of Edward P. Warner. It is not good government practice nor is it the best thing for aviation for the federal government to smash the national development. It encourages the localities to do the job.

It is too late to control traffic when accumulated until it is entering a traffic control airport. Control in terms of time and altitude must extend from take-off to landing and the question of whether a commercial airplane is a traffic control tower can continue jurisdiction over aircraft over another state is still to be determined in the opinion of New Jersey State Commissioner Giff Zalka Wilson.

What future planes should be like

Future plane features should include perfect stability, elimination of spin, stability in stall, glide path control, braking speed to an automobile, a wide range of landing speeds, and two controls. It is also desirable to have maximum flying speed below 35 mph and ability to climb out of a stall; hold New low landing speed but low climb speed is desirable. There is such wide chance of surviving a crash at 35 mph than one at higher speed. Flying altitude is reduced on the basis of crash danger and pleasure of flying is directly proportional to altitude. Another development for safe landing may be the airplane parachute but this is only for small planes.

Radio requirements already have dated at least one airport to the private flyer. Other considerations will follow. It will then be necessary to move out to smaller fields and the plane of the future must be built for these. Landing strips and roadside places offer an excellent solution. The variable altitude is already successful and the Wisconsin roadside traffic plane is now operating on the Coast (read speed, 100 m p h).

(Continued on page 90)

POUNDS

Power plant design and aerodynamics have reached a state of development where some radical innovation will have to be introduced to ensure any noticeable acceleration in the rate of progress. In structural design, however, there still remain real opportunities to increase overall efficiency. The author's study of strength weight relationships points up some of them. The first of two articles.

Pounds or Square Inch

By F. H. Shanley*

*Although the author is a member of the staff of the Bureau of the Commissioner, this article reflects his opinions as an individual citizen.

If there were a standard of construction, designers have become fully aware of the fact that the commonly used strength-weight factors for various materials are of small significance. There is a general understanding that stiffness because of gross inhomogeneity than strength in many cases. Yield strength are almost always of greater interest than ultimate tensile strength. A clear concept of all the various factors involved will not only indicate the relative merit of different materials but will explain why certain types of construction are more efficient than others and will also give some idea of what to expect in the future.

Before proceeding further consider just what the term "strength-weight

factor" means. (The term "factor" is here used instead of the more usual term "ratio".) It certainly is not a dimensionless, at least in its usual form. Some method of including it in a coefficient form (as that it would have the same value in all systems of measurement) could probably be worked out by establishing standard and basic dimensions. This will not be attempted here, however, as we are concerned with the comparative merits of different materials, not in the individual factors for each material.

As will be shown later, in some cases there is actually a large material difference in the results obtained by using "strength-weight" or "weight-strength" factors. We shall therefore consider "strength-weight" as meaning the ratio

of strength for constant weight, assuming the same dimensions to be held constant. Conversely, "weight-strength" means the ratio of weights for constant strength, under the same general conditions. The designer will usually be more interested in "weight-strength" factors, as the strength required to come in line is independent of the material or type of construction, and the object is to reduce the structural weight as much as possible. Very little is to be gained by increasing strength beyond certain limits but there is no apparent limit to the increase in pay load obtainable by reducing the structural weight. On the "strength-weight" basis pay is delivery,

Figure 1. Comparison of Three Basic Materials with Respect to Stability Failures of the Shell Under Compression or Bending.

These two factors are obviously reciprocal and either can be used in comparing different materials.

Geometry of the structure

In dealing with Type II failures it is necessary to know something about the geometry of the structure. The weight cost of a round tube at compression can be used as a basis, as the results can be shown to apply to more general cases. Assuming that the round tube represents a baseline, for instance, we can take the diameter ($2a$) as constant, leaving the wall thickness (δ) variable. The critical stress at which the walls will buckle due to instability has the general form (NACA Report No. 474):

$$F_c = K E \delta^2 / a^2 \quad (3)$$

Since the strength, S , equals F_c/A (where A is the cross-sectional area), and since the cross-sectional weight, W , is proportional to wall thickness δ , the strength factor becomes an interesting factor for F_c and controlling constant:

$$(S/W)a = C(\delta/a) \quad (4)$$

$$(W/S)a = C(a/\delta) \quad (5)$$

These results can be derived for the case of bending failures and will represent universal stability factors fairly well also. (It can be shown that for torsion a good approximation is obtained by raising to the 5/4 power, but such refinements will be left for further development.)

The strength-weight factors as far derived for Case II are interesting in that they show that the failing stress, F , for "stresses" follows in reciprocal by the factor A . This result, however, is not new and fails to give us a factor which is a function only of the material. Our problem now is to eliminate F from Equations (4) and (5). It is here that the new idea of holding either the weight or the strength constant gives us a clue in the solution.

Since we are usually dealing with constant strength, consider that case first. The total strength against compressive failure due to instability is equal to $F_c A$, where F_c is found from Equation (3) and A is the cross-sectional area. Replacing A by its value for a thin-walled tube ($2\pi a \delta$) and again employing a general constant, we get

$$S = C \delta^2 / a^2 \quad (6)$$

If the strength, S , is held constant, Equation (6) can be solved for δ , giving

$$\delta = C \sqrt{a/S} \quad (7)$$

Substituting this in Equation (5) we

AVIATION
November, 1958

get the answer, for the case of constant strength, in the form

$$(W/S)a = C (\pi/a^2) \delta \quad (8)$$

By a similar process, holding the weight constant, the solution can be made for the "strength-weight" factor,

$$(S/W)a = C (E/a^2) \delta^2 \quad (9)$$

The results are summarized in Table I.

TABLE I FACTORS AFFECTING STRENGTH AND WEIGHT OF TUBE-TYPE STRUCTURES BASED UPON BUCKLING OF SHELLS			
	TYPE I, TUBE	TYPE II, TUBE	TYPE III, TUBE
	Stress-Through	Stress-Through	Stress-Through
W/S (Strength/Weight)	1/a	1/a	1/a
S/W (Weight/Strength)	1/a	1/a	1/a
W/S (Strength/Weight)	1/a	1/a	1/a
S/W (Weight/Strength)	1/a	1/a	1/a
W/S (Strength/Weight)	1/a	1/a	1/a
S/W (Weight/Strength)	1/a	1/a	1/a
W/S (Strength/Weight)	1/a	1/a	1/a
S/W (Weight/Strength)	1/a	1/a	1/a
W/S (Strength/Weight)	1/a	1/a	1/a
S/W (Weight/Strength)	1/a	1/a	1/a

Comparing the two results, we find that the strength-weight factor is not the reciprocal of the weight-strength factor in the case of monocoque structures which fail through instability. It is, in fact, proportional to the square of the reciprocal. As a simple illustration of what this means, assume that two aluminum structures are required to support a load of 1000 lbs. and that the structures are required to have the same weight. If the weight-strength factor of the two materials are in the ratio of 1 to 2, the structure weights will also vary in this proportion. It, however, the weight of the two structures are held constant, one will be 16 times as strong as the other. This

result, although somewhat surprising, is of an equal interest except to indicate the importance of choosing the proper factor to work with. It does, however, have some application in connection with military aircraft which are built to high strengths.

An important condition which can be derived from the new weight-strength factor for monocoque shells is that the influence of E is greatly reduced in comparison with the influence of π , the unit weight. This should be of interest to those who have had experience in the fact that certain aluminum alloys, which usually have low values of E/π . Since it is almost impossible to do much about changing the modulus of elasticity (E) of any material, it is encouraging to find that it is not so important after all. It is obvious, however, that the unit weight, π , is very important and that much can be done along the line of reducing π . In a later article it will be shown that most modern structures employing high-strength materials usually represent an artificial reduction in the cross-sectional weight by an extension in the effective thickness of the shell.

Without going into the many secondary factors that influence the choice of a material and type of construction, it will be of interest to see how these basic factors look when applied to some actual materials. In Table II the ratios of these factors have been computed for the three common structural materials, using arbitrary values for E and π . (These are of course subject to modification when applied to non-homogeneous construction and could be further modified to account for other factors, such as Poisson's ratio). The ratios of E/π are included to show how radically the new factors differ from those commonly employed. Although E/π is usually the case for all three materials, the table shows that a steel rib would weigh

about 28 times a wood shell of equal strength. When considering equal weights, it appears that the wood shell would be nearly 15 times as strong as the steel and 7.5 times as strong as one of aluminum alloy. The relationships can be visualized by referring to Fig. 3, which needs no further explanation.

Extending the method

Obviously the method of attack can be extended to include intermediate types of failure and it offers a new approach to the general solution of the monocoque strength problem. Present methods of construction can be evaluated on this basis, but the most interesting possibilities appear to be in the application of the theory to new materials and new forms of construction. The next article in this series will cover these points in greater detail.

*

Rib Fabricator

Taylor develops machine to stress ribs in quantity

A device for fast and economical construction of airplane ribs has been developed by the Taylor Aircraft Company. The machine is a high speed presser which positions and crimps the aluminum alloy sheet without moving the work between operations. The operation places the constructed stock in the rib jig and guides the jig to the correct place for crimp. Provision on one foot pedal guides the hole and a second pedal is provided for the riving operation. The point that made stand up perfectly in static tests.

The Taylor rib fabricator machine.

while with the "weight-strength" the objective is the reduction of the structural weight toward zero. Although it often an attractive subject for speculation and debate, we shall not attempt to prove that it is easier to approach zero than infinity, although into structural weight seems to be a more reasonable and practical objective than infinite strength.

Wing and fuselage

The two practical cases in which we are most interested at present are the wing and the fuselage. We shall begin by assuming that the external dimensions have been decided so and that they are to remain substantially unchanged. That leaves the designer with a choice of material and type of structure. Since there are an infinite variety of structural types, it is easiest to consider two extreme cases and then to evaluate the results when dealing with intermediate forms of construction.

We therefore reduce all stressed-skin structures to two basic types, classified as to the nature of the failure. Type I is that in which failure occurs at some definite stress, which is a function of the

material only. It could be either the stress at tensile stress, or the yield stress. For simplicity we can refer to this limiting type of failure as a "stress failure." For Type II failure occurs through instability of the structure. Such failures depend essentially on the dimensions of the structure and the elastic properties of the material. The actual value of the stress has no direct significance, except in cases where it affects the elastic properties. We can conveniently refer to the sort of failure as a "stability failure."

It will be unnecessary to derive the strength-weight factors for Type I failures, as it is obvious that the two basic structural characteristics involved are the failing stress and the unit weight. If we denote the failing stress by F , and unit weight by π , the strength-weight factor will be proportional to F/π and the weight-strength factor will vary as π/F . We can avoid difficulties about units of measurement by using arbitrary constants which will cancel out when comparing different materials. The two factors for Type I failures then become:

$$(S/W)a = C (F/\pi) \quad (1)$$

$$(W/S)a = C (\pi/F) \quad (2)$$

How FAST?

1. Ultimate Maximum Speed at Sea-level

The first of a series of articles discussing the upper limits of airplane performance. Later articles will cover speed at altitude, range and ceiling

It was not until 1921 that any airplane officially exceeded 200 m.p.h. in level flight for even a few minutes, but within thirteen years that speed had been more than doubled. It has long been interesting to speculate as to the future course of the graph shown in Fig. 1.

It is an interesting thought nevertheless, that the maxima of the record appear to be along a line whose slope is approximately 15 m.p.h. per annum, a rate of record-speed increase which is surprisingly low from some angles, surprisingly high from others. These records have all been made at sea-level, so far—but new landplane records will unquestionably be recognized at high altitudes in the near future.

The Hughes racer, which did 312 m.p.h. at sea-level after a 1200 foot starting dash, would, if it could sustain the same thrust horsepower at altitude with a corresponding drag-start and, do 336 m.p.h. at 30,000 ft and 426 m.p.h. at 20,000 ft. Speed attainable at altitude, however, involves considerations quite different from those connected with speed at sea-level, due mainly to the large role played by the increased drag at altitude, and is therefore to be treated separately.

If we restrict ourselves to speed at sea-level the induced drag becomes negligible for small, high-speed airplanes. A consideration of the thrust horsepower required at sea-level then gives a simple picture of the difficulties ahead in attempts to raise the present record.

With induced drag neglected, elementary aerodynamics indicates that the

Fig. 1. How fast—sea record of airplane speeds from the early Langley era to the North American.

following mathematical relations exist:

$$\text{where } P = \text{the thrust, horizontal velocity at sea-level is m.p.h., } P = \text{the brake horsepower, } \eta = \text{the overall propulsive efficiency, } (u/V) = \text{the thrust horsepower, and } f = \text{the equivalent parasite area in square feet, defined as the ratio of the parasite drag in pounds to the dynamic pressure in pounds per square foot.}$$

The quantity (u/V) might well be termed the minimum "cost" of speed, since it is, effectively, the minimum thrust horsepower required per square foot of equivalent parasite area for any given sea-level speed. Fig. 2 shows how in-

creased rapidly this "cost" rises with speed. This plot of the above equation does not present the complete picture due to the absence of any allowance for induced drag, and also due to the fact that straight-away speed records usually have the advantage of some diving start. The advantages gained from the latter fact, however, like the loss from the induced drag, decrease with increasing speed.

As an example of the price to be paid in increasing speed, two transport airplanes are shown in Fig. 2 for comparison with three famous racing planes. The comparison gap between the Ford Trimotor and the Douglas DST is well-known but it is useful in terms of the "cost" of very high speeds.

Gradually, the way to meet the price is to increase power and decrease drag and these become more and more difficult to do satisfactorily.

The price limit

Inasmuch as there is a definite limit below which drag cannot be reduced,

The North American's record holds of the world's absolute speed record.

then as speed is increased there is reached a value above which the only way to meet the price is to increase the power faster than the drag. But even this cannot be continued indefinitely for conventional designs—a point is finally reached where we cannot pay.

The limiting price is set by the phenomenon of compressibility, which quickly becomes ever more active in bounding the question as the velocity of sound is approached.

Mr. Stull, of the N.A.C.A., is the first name of the Journal of the Aeronautical Sciences, showed that, for a hypothetical, very dense conventional design, the drag increases due to the compressibility factor becomes too great to overcome at about 420 m.p.h. An estimate based on Stull's data is included in Fig. 2.

While the price is extremely difficult to meet at over 360 m.p.h., the authors hesitate to place the absolute limit below 75 percent of the velocity of sound, i.e., at about 273 m.p.h., though to approach this limit would undoubtedly require radical changes of wing and fuselage form: in contrast, the compressibility price limit.

Future record holder

The question naturally arises: What kind of an airplane will possibly exceed the present absolute record? So many possibilities and difficulties are involved that the authors do not care to go so far as to present a three-view of what the plane might be like.

It is felt that the airplane cannot raise its record very materially, unless reasonable fuels can be employed. However, there is plenty of room for improvement in the landplane record. The price for the Macchi Caravello was met largely by the use of a great amount of power (3300 brake horsepower)—that for the speeds made by the Conquest-Burns was met more by low drag. Both methods of paying must be used—but at the same time the landing

speed must be kept down to not much more than 100 m.p.h., so that complicated high lift devices will be necessary if extremely high wing-loadings are used, but they do not present insurmountable difficulties. (An alternative might possibly be a variable-wing-area arrangement, such as is used, for instance, on the "Vernor" airplane now under development in France.) A different type of engine than that used to set the present landplane record will probably be required.

Flying engines

Suppose that we have a single-row radial engine of 55 in. diameter (bore), 16.5 sq. ft. developing 1250 brake hp. for racing purposes. Consider the feasibility of this engine, with its propeller and cowling and a static load, flying level through the air by itself. Then the equivalent parasite area would be about 1.5 sq. ft., so that for an overall propulsive effi-

Fig. 3. "Cost" of Altitude Speed in Terms of Thrust and Cowling.

ciency, and radiator, should have an equivalent parasite area of only 3/4 sq. ft., which for 75 percent efficiency would correspond to a maximum parasite area-speed of about 335 m.p.h.

Thus in the above hypothetical case, whether or not the comparison may be considered as entirely fair, there is a 21 per cent speed increase and an 18 percent power decrease in going from the first engine to the second.

In doing the authors would like to say an acknowledgment in the present American development of compact high-power a.v. and liquid-cooled in line and horizontally opposed engines. Their necessity, from the viewpoint of very high speed, should be obvious for we not only are directly racing planes, but in pursuit and fighter planes as well, their desirability for some of the larger types follows also. It is to be hoped that at least a fraction of the research work which has been devoted in the past to radial engine installations will be directed toward in-line cooling and cowling problems, and especially to the development of propeller motors designed specifically for in-line engines.

The North American X-15 holds the world's absolute speed record.

The Douglas DST holds the world's absolute speed record.

Editorials

AVIATION & HYDROAERONAUTICS
VOLUME 8, NUMBER 11

HOME THOUGHTS FROM ABROAD

THE life may seem a bit prosaic in this as being written in New York, but by the time this issue of AVIATION goes into print it will be quite appropriate, for our editor will be in England on the first leg of an extended cruise that will cover a remarkable portion of Europe and will wind up at the International Aeronautic Salon in Paris, late in November.

No pocket that, but a part of a long-extended program of world wide coverage. AVIATION has never before seen a step-by-step, point-point and ordinary life. It has always taken every opportunity to get out and see for itself. Even through the depths of depression, when expenses had to be cut to the bone, the editorial staff was travelling, visiting factories, manufacturing shops and airports. In the last years they have bagged over 50,000 miles, up and down the country's shores, from the Atlantic to the Pacific, and from Canada to Panama.

So once more we are treading our perennial situation to Europe. It is not a new idea, for our distinguished predecessor made several trips abroad during his editorship of AVIATION. His wide acquaintance with people and affairs outside of the United States have been invaluable to the proper conduct of this magazine in recent years.

At this time we hope to contribute our own criticism to Europe, and to bring back to the readers of AVIATION a firsthand picture of European aviation today. This is especially important at this time when commercial aviation of all countries are extending themselves to include the globe, and when the economic political state of Europe is reflected in developments and construction of military aircraft as in a supercharged scale.

In carrying out a program of this sort we are not continuing the picture laid down by the founder of AVIATION twenty years ago. He saw then that the interests of the magazine were international in scope—after sixteen people all over the world had a common interest that transcended national boundaries. Our purpose is to carry on with that idea, to report without fear or favor—without malice and without political bias—events and movements of interest to the aviation industry all over the world.

JERSEY JUSTICE

THE State of New Jersey has long been operating a very lenient policy for the prosecution of lightness and qualified fixed base operators that may well be made a part of other state aviation programs. Before we are more lenient on New Jersey airport and air up on the flying business, we must receive the approval of Gill Robb Wilson's Aviation Commission.

And the granting of the approval is an more adequate formula. The

aviation's history, both personal and business is thoroughly investigated. Short industry carries a much weight as financial responsibility, and his operating plan also is subjected to the closest scrutiny. But only meet his equipment he of approval type, but the airport and its surroundings must meet all state requirements for safety and soundness and have safe approach.

Once he has been passed upon, however, he may set up his business as he chooses, provided that an inexperienced operator will be permitted to

operate down in his territory to child care his profits by changing the course of the seasonal business and then moving on. This in itself is a great contribution to safety, for the operator can then spend his money on good equipment and for adequate maintenance, with full assurance that his rights will be protected.

The removal of unrestricted out-of-state competition through this form of state control has undoubtedly contributed greatly to New Jersey's excellent safety record of the past few years.

RAIL AND FAREWELL

DEPARTING from Lubbock on a night that kept all other forms of aircraft grounded, the Zepppelin Hindenburg completed the last of the commercial schedule of its second flight between Germany and the United States for the 1936 season. Few commercial projects of such proportions have ever tested their potential for performance as has this season's expedition of the Zepppelin Hindenburg. Those of us who have watched her regular crossings and good luck could not fail to be surprised with the efficiency and dispatch which have surrounded her visits. Those who have had the good fortune to travel on the Hindenburg have been told in their process of embarkment. The only complaint which has reached us has concerned the general lack of excitement connected with the trips.

There is no question but that considerable public interest has been aroused in the possibilities of lighter-than-air travel. We cannot help but feel that this season's work has done a great deal to effect the effects of the unfortunate experience of the past. A view in the wind is Col. J. Maurice Johnson's announcement that he is preparing an amendment to the Harmon Act which would be designed to strike the same financial support provided for surface craft. This covers two major features, (1) a guarantee that a flightable world and the United States, only the rest of a slender ship built in a foreign country, and (2) any differential in the cost of operating on airship in comparison with the operating costs of any foreign company would be met by the U. S. government.

We look forward confidently to a rebirth of sufficient interest in this type on the United States to lead to the establishment of a sound program for commercial lighter-than-air development under our own flag.

Flying Equipment

How's new in aircraft, engines and major accessories

Roadable Autogiro

Jim Ray delivers new machine by landing in park and driving up to Commerce Department door

Largely on roads as in city streets is something most pilots do once in a while—so to James G. Ray, vice-president of the Autogiro Company of America, it is commonplace. Jim's most recent venture was the delivery of the new "roadable" autogiro at the front door of the Commerce Building in Washington. Although the roadable gyro is designed to be driven home from the airport, Jim Ray didn't follow the formula at Washington. Instead he landed in a small Commerce yard near the Commerce Building, fished his notes and drove to his destination. Delivery was made formally in the presence of Air Commerce Division Express L. Vail, Secretary Daniel C. Rogers and Col. J. Maurice Johnson, Assistant Secretary of Commerce. Passenger on the flight to Washington was John H. Greese, Chief of the Development Section of the Bureau. Following the delivery a series of acceptance tests were scheduled at Bolling Field.

Designed to combat the handicap of inaccessibility of airports from centers of population, the new gyro is distinguished from its predecessor chiefly by the roadability feature. This demanded a change from the conventional engine location to provide for the transmission of power to the rear wheel, which is the driving wheel on the road. The location selected for the engine was behind the cockpit with one drive shaft running back to the rear wheel and another running forward through the cockpit to a gear box which transmits power to the master propellers and to the rotor hub for starting.

Several times in the last year we have stopped in at Willow Grove, to watch progress on construction of the gyro. So we have seen it both driven and parked, as it were. The accompanying drawing gives a good idea of its internal arrangement. In preparing the drawing of the autogiro, however, it is obvious that some changes have been made in recent months.

Most apparent is around the nose where the double propeller mechanism has been abandoned in favor of a single propeller. The combination did not give

the desired results as far as torque elimination is concerned, and besides made a serious error in flight. This led to a situation in the gyro's design that was being corrected. When the combination was replaced by the single prop the nose shape was modified considerably, the older rounded and very blunt lines were considerably modified to a more pointed form, which we

understand has improved the speed characteristic considerably.

By making closer comparisons also, it will be noted that the tail surfaces have been modified. The first form was of a completely cellular type. When the ship was delivered, however, a monoplane stabilizer, a normal fin, a small rudder and elevator and plane appeared.

The landing and the struts looking up the rotor poles are of welded steel tubes. An interesting feature of the landing gear is the second air wheel. Each wheel is mounted on a swiveling knuckle, somewhat similar to ordinary automobile wheel steering. By means of cables and tie-rods, the wheels are hooked up to the rotor poles

The Roadable Autogiro in its early stage

Finally in a Washington work

Hoisting in India

With this consideration, the ship is said to be very maneuverable on the ground.

One gets an impression of extremely small size when first looking at the machine, but after entering the cabin, one finds plenty of room, comparable to the average small closed airplane. The propeller drive shaft passes forward between the two seats forming a sort of aisle-vent and providing a pedestal on which the rudder control, stick control, etc., are mounted. The control stick is suspended from the roof. When out in use, it swings forward and is held out of the way by a spring clip on one of the pilot's seat-belts. Vision from both seats is excellent in all necessary directions. There is very little electronic forward, because the propeller shaft and associated bearings are in very small bearings.

No trouble has been encountered, either on the ground or as the ship is being hoisted by the hoist in its semi-vertical position. Air is drawn up underneath the fuselage, passing through the lower section and is discharged through sets of louvers along the fuselage side.

The reliable ship has a top speed of 99 m.p.h. and sufficient fuel and oil are carried for 3½ hr. cruising flight with pilot and passenger and 4½ hr. of hop-ping. Maximum speed is 29 m.p.h. and it is designed to take off in less than 150 ft. with no wind. Additional performance data will be released following the test flights.

Aeroneer Tested

Production of 25 Ships to Follow Completion of Flights

Future "Aeroneer" is dedicated to the Glennon team. Flight and performance testing is now being completed. Production of a group of 25 of these ships is scheduled to be started in the near future.

Early flights of the first Aeroneer were made during the National Air Races and much favorable comment was received by the manufacturers.

Aeroneer Seaplane

Low wing model based on Edo floats

Construction of seaplane floats for the wheel type landing gear of the new wing Aeroneer was made without decreasing the useful load allowance. The ship is a seaplane in concept for two persons, 26 gal. gasoline, 3 gal. oil, battery, starter, and 75 lb. of luggage, bringing

the gross weight up to 1,882 lb. Test flights of the new seaplane were made recently by J. C. Wilcox, sales manager of the Aeronautical Corporation of Japan, at the plant of the Edo Aircraft Corporation, whose model 7905 seaplane floats are used. The engine is the 90 hp. Warner.

"Time Flies"

Tests underway on Frank Hawk's Monoplane

Preliminary details of Frank Hawk's new plane, "Time Flies" were published in the October issue of AVIATION. At that time there was no pictorial material available. We are now able to present photographs and three view drawings of the ship that is expected to make many records. During the construction of the new ship, Hawk has lived with the job and is now getting the ship through its paces in flight in an equally serious manner.

Details of the structure, retractable wheeling mechanism, and other design features were discussed in the previous article in AVIATION. General features of the Aeroneer equipment include the mechanism of the new Sperry gyroscopic compass, a combination of the gyro and magnetic compasses. A Brexer exhaust gas analyzer is also installed on the ship. In addition is the complete radio equipment, an ultra high frequency transmitter and receiver (3-5 meter band) has been built into the ship.

Aeroneer Hawk under test flying Aeroneer in Canada.

Stearman powered Aeroneer in flight

Stearman powered Aeroneer primary trainer

The engine is an 8-450 BG Twin Wasp developing 1150 hp. at sea level, equipped with automatic mixture control. A Blaudt-Staubert constant speed propeller is used.

Stearman PT-13

Model 75 now by Army as primary trainer

The primary training at Randolph Field, Austin, Tex. is made of the PT-13, Stearman Model 75 biplane powered with the Lycoming R-680-5 engine. The PT-13 is a two place tandem open ship with wooden wings, welded shape mild-steel main fuselage, and fabric covering. Tail surfaces are similar in construction to the fuselage. Wing span of the PT-13 is 35 ft. 2 in.; overall length, 25 ft. 4 in.; weight empty, 1,850 lb.; and gross weight,

Type 92B by Frank Hawk

2,995 lb. High speed at sea level is 225 m.p.h., cruising speed (sea level), 100 m.p.h., service ceiling 14,000 ft., and cruising range, 412 miles.

Mitsubishi Monoplane

Two designs by Japanese Government Railways

THE JAPANESE GOVERNMENT RAILWAYS has designed two airplanes equipped with all the necessary instruments for emergency and emergency purposes. Both are single engine high-wing monoplanes. One of them, built by Mitsubishi, was remodeled from the Army's "92" type reconnaissance plane, which is equipped with a 475-hp. Mitsubishi Japen armoured model engine developing 408 hp. at 2,000 rpm. Weight empty is 1,060 kg. (2,332 lb.) and gross weight is 1,800 kg. (3,968 lb.), exclusive of armament equipment. The plane has the following general dimensions:

Wing span 12.700 m. (41 ft. 8 in.); length overall 8.535 m. (28 ft. 4 in.); wing area 26 sq. m. (286 sq. ft.).

According to the "Kokai Jiken," the machine is capable of a normal level flying speed of about 195 km. per hour (118 m.p.h.) a top level speed of 250 km. per hour (150 m.p.h.) and can climb to a ceiling of 4,000 m. (13,120 ft.). The "Kokai Jiken" reports that it develops a top speed of 220 km. per hour (135 m.p.h.) at an altitude of 1,000 m. (3,280 ft.) and 212 km. per hour (193 m.p.h.) at 3,000 m. (9,842 ft.). Both figures list its cruising speed at 980 km. (595 m.p.h.).

The other monoplane, which is still in the course of construction, has been remodeled from the "95-2" type training plane of the Imperial Army, which

(Continued on page 35)

Balanced distillation characteristics

reduce carburetor icing

Lower temperatures . . . without freezing . . .
give greater power output

YOU can lower the temperature of your "hot spot" and still reduce the possibility of icing.

This exceptional performance is only possible when the distillation temperatures at 10%, 50% and 90% of the volume are held to exacting limits and bear a definite ratio to each other. Because Texaco has access to all types of crudes, Texaco refiners select only those crudes that have the necessary characteristics to maintain this balance.

Texaco Aviation Gasoline is processed by exacting refining methods that enable us to control the ratio of these temperatures exactly.

Because of this you get a uniform product that gives added margin of

safety in the operation of your planes. The reduction of temperature helps to obtain greater power output from your engines. We invite you to make your own tests of this product.

Our aviation engineering staff and extensive laboratory and testing facilities are at your disposal.

NEW
BASIC
TRAINERS

To acquaint army cadets with an important feature of high-performance aircraft, the new basic training ships of North American and Stearman are now equipped with Hamilton Standard Controllable Propellers. . . , further evidence of the widespread use of the controllable prop principle.

HAMILTON STANDARD PROPELLERS
EAST HARTFORD, CONNECTICUT
DIVISION OF UNITED AIRCRAFT CORPORATION

Koellhoven Junior is two place monoplane.

Koellhoven Junior

Two place all wood monoplane has clean lines.

A CLEAN looking two place open monoplane has just been introduced by Koellhoven in The Netherlands. The Junior (Model P.K. 52) is somewhat unusual in appearance in that the main wing panels are located at about one-half the height of the fuselage and connected by short stub wings to the lower fuselage, giving a pronounced gull effect. This arrangement combines the desirable weight distribution of a center wing monoplane with the good visibility of the low wing type.

Wood construction is used for the most part. The wing is built up of two spars and three ply ribs, the whole being integral with the fuselage which is made up of three ply with spruce longitudinal. Outer wing panels are easily detachable from the control unit. Plywood is used principally for the covering of wing and fuselage. The tail unit is of construction similar to the fuselage and is integral with it.

Landing gear consists of two separate wheels located in the wing stubs. Shock absorbers in compression constitute the shock absorbers.

The power plant is a 30 by Walter Moors and the engine mounting is of welded steel tubing.

Wing span of the P.K. 52 is 30.5 m. (100 ft.); length, 7.2 m. (23 ft. 6 in.); and area, 15.5 sq. m. (167 sq. ft.). Weight empty is 275 kg. (605 lb.) and gross weight, 400 kg. (882 lb.). Maximum speed is 130 km. per hour (80 m.p.h.); cruising speed, 125 km. per hour (78 m.p.h.) (both at sea level) and landing speed is 60 km. per hour (37 m.p.h.). Service ceiling is 2,800 m. (9,186 ft.) and range varies from 205 km. (128 miles) to 1,300 km. (808 miles).

Breda 79, 79S

Two new Italian ships for private flying.

A new series for private flying and touring has just been introduced in Italy by Breda. Two models—the 79 and 79S—are available. The former is

powered by the 110-hp. Alfa Romeo engine while the latter uses a 115-hp. hp. power plant of the same make. Both of the engines used are overrated, in fact.

Structurally the Breda 79 and 79S are similar. Both have wooden wings with plywood and fabric covering, metal fuselages with fabric and aluminum alloy covering and metal tail surfaces with fabric covering.

Dimensions for both models are: wing span, 11.61 m. (38 ft.); length, 7.60 m. (25 ft.); height, 1.57 m. (5 ft. 2 in.); wing area, 20 sq. m. (219 sq. ft.). Maximum speeds are: (79), 210 km. per hour (130 m.p.h.); (79S), 200 km. per hour (124 m.p.h.). Minimum speeds are: (79), 70 km. per hour (44 m.p.h.); (79S), 75 km. per hour (47 m.p.h.). Range of the 79 is 200-1,300 km. (124-808 mi.) and for the 79S is 200-1,200 km. (124-744 mi.).

Do 22 with 100 hp. Daimler-Benz engine.

Breda Model 79 with 110 hp. engine engine.

Dornier Do 22

New three seat bomber and reconnaissance airplane.

A LIGHT bomber, torpedo bomber, or long distance reconnaissance plane, the Do 22, has just been released by the Dornier Works of Friedrichshafen, Germany. Accommodation for three—two pilot, observer, and gunner, are provided in the metal fuselage of this two seat airplane. The oval section fuselage is built up of welded steel tubing with duralumin bulkheads. Sheet metal and fabric coverings are used. The wing structure is of duralumin with fabric covering. Tail surfaces are of duralumin with fabric covering. Compression is obtained by metal auxiliary surfaces above the stabilizer.

Various engines ranging from 700 to 900 hp. can be used. The model shown here is powered by an 800 hp. Hispano-Suiza, radial-cylinder engine.

Span of the Do 22 is, 16.2 m. (53 ft.); overall length, 12 m. (39 ft.); overall height, 4.7 m. (15 ft.) and wing area, 43 sq. m. (464 sq. ft.). Weight empty is 2,220 kg. (4,912 lb.) and normal gross weight, 3,550 kg. (7,838 lb.); maximum gross weight, 4,000 kg. (8,818 lb.). Maximum speed is 320 km. per hour (199 m.p.h.); landing speed, 52 km. per hour (31 m.p.h.); ceiling is 5,200 m. (17,075 ft.).

Take off in Safety Land in Safety on runways of CONCRETE

Rhode Island State Airport runways are each 3,600 ft. long by 150 ft. wide. Permanent concrete of first 30-ft. surface patch of 4-6-8 mix, even section, installed into 1941 (upper view).

The first takeoff from the new Detroit Municipal Airport at Van Dyke, Mich. Progress hastened by WPA funds.

Concrete's safety makes our walks from the airport to the incoming plane. For pilots can see light-colored concrete runway night or day. And when the plane lands down it has a smooth track to land on with ample drainage for rain—or excessive snow, no puddles of standing water, no ruts or bumps.

Concrete's durability and safety improve ground facilities, help attract business to any airport. Concrete is serviced in good weather or bad, shortens takeoff time, is free from loose particles to be picked up by the propeller stream, endangering passengers and planes.

And the cost? Surprisingly low. For concrete runways can be designed economically for given wheel loads and landing weights with ample safety factors. Concrete stands up under heavy loads, withstands in moderate first cost with long life and relatively low maintenance charges.

For policy, for service and for further economy, your airport architect should be concrete. Let us help you plan it by sending free Information Sheet and the booklet, "Concrete Makes Airports."

Carlin's Patent's hoist.

Hydraulic Hoist

Elevators have a number of aeronautical applications.

An ingenious hydraulic hoist of the type found in many garages, have been applied to a number of aviation activities (see Maintenance Notebook). A complete line of equipment of this sort is manufactured by the Carlin's Pneumatic Machinery Company of St. Louis, Mo. These elevators are of the plunger type, operated either by air pressure above the oil in a separate reservoir or directly by pressure developed by an absolutely oilless air pump. The operating cylinders are designed to be set vertically into the ground. A wide variety of piston depths is available for specific applications.

Retractable Light

Delco announces hydraulic retractable landing lights.

A new series of landing lights for aircraft has been designed and is introduced by Delco, Detroit, Mich. Long Beach, Cal. Air Association is handling sales on this equipment.

The Delco light is designed to be built into the under surface of an airplane wing when not in use. When extended hydraulically, it moves through an arc of 90 deg. forward and forward. The light is hydraulically operated from a small control box in the cockpit through a single line of flexible tubing. A stake arrangement per-

Buyers' Log Book

What's New in Accessories, Materials, Supplies, and Equipment

sets the light to be adjusted at any one of fifteen intermediate angles. The pair of lights and the control box with 7 in. selector (S25,000; cost/power) weigh approximately 24 lb.

To meet transport requirements, a new light with a 17-in. diameter reflector, designed to be mounted in the under part of an airplane fuselage is being developed.

The Fitchell-Hesson Fathin Fluke.

Instrument an observer needs only the vertical flange, and a clock giving Greenwich civil time. It may be hand-held for an observation or it may be placed in a gaud. The instrument was invented by Mr. Fred C. Hagan of San Antonio, Texas.

Aircraft Skis

Snow equipment designed for light plane service.

ACROW/REINER has been received from Air Transport Equipment, Inc., of Rosemead Field, Gardn City, N. Y., of new snow equipment, designed particularly for airplanes of the Taylor Cub or Aerocub class. They are made of oak reinforced with brass runners. The attachment points are made of aluminum-aluminum alloy steel tubing fitted over the regular wheel axle of the airplane on prepacked brass bushings.

The Model A skis are manufactured under license of Air Transport Equipment type certificate No. 66 for airplanes whose gross weight does not exceed 575 lb.

The new Defco light mounted and retracted.

Position Finder

New instrument developed by Fairchild for navigation calculations.

THE FAIRCHILD Position Finder is the latest in navigation equipment developed by the Fairchild Aerial Camera Corporation at Woodbury, L. I., N. Y. It is substantially a slide rule instrument which permits obtaining a "fix" in a much shorter time than with the standard equipment. The primary purpose is to eliminate much of the complicated computations necessary in the usual method of position determination.

It is a compact instrument of high precision which may be considered a miniature celestial sphere. It contains principally of a horizon plane, declination arc, altitude arc, altitude arc and hour angle circle. The horizon plane carries the altitude arc, altitude circle and a circle level bubble. With the in-

Air Transport equipment Model A Skis on a Taylor Cub.

Operators' Corner

An exchange of ideas on the problems of the commercial aviation industry

WHAT is to be done about the problem of the young aviator who has learned to fly with no standardized operation and wants to go into airlines? Are there? Should the pilot attend commercial class for a minimum of twelve hours, or should it be a one or two-year program? Is it worth the cost of the pilot's time to add him to a ship, and an operator for the time and effort to the operating schedule? Should the other aircraft operator be the one to be instructed about?

Helps plane sales

EVERY student pilot is a potential future member of the commercial aviation team in one or several capacities. All flying school operators are conscious of this fact and many feature their ability to place the newly graduated pilot in a career qualified for such work. It is obvious that a small proportion of student pilots only look upon commercial aviation as a probable vocation, many learning to fly for private purposes or recreation only. It is my belief that the flying school should not regard potential operators developing from student pilots as competitors to it or inevitable that the field will expand and develop.

It would appear good advertising on the part of a flying school to attract prospective students by offering the service of something them to become established as operators when they are qualified. Frustrated from plane sales activity is a considerable factor in flying school receipts and should be encouraged. I feel that the benefits to the flying schools following this practice more than offset the value of the other experience. —*Ernest A. Dwyer, Dwyer Flying Service, Inc., Dwyer Airport, Los Angeles, Cal.*

Newcomers not competitors

THIS question is right up our ally and asked accordingly. First we do not view a newcomer as a competitor but as a welcome brother in the fraternity.

Over a period of years we have accumulated a wealth of information on just how to help a new operator get started in the aviation business. If he is a student of ours he has ample opportunity while learning to fly to learn our methods of maintenance and operation. Then when he starts on airport he knows just what to do and how to do it. We not only show him but give him actual practice in selling airplanes, flying contracts, and passenger flying the proper way to instruct students in order

to make them good, safe pilots; how to maintain equipment and to operate correctly; how to utilize every valuable moment that is made available; how to dig away, how to write advertising and get acceptance but valuable publicity and a source of other work. The conditions of which is bound to make anyone successful in aviation.

We have helped several young fellows get started this year and we have more plans to get new operators than we have operators to put in them. One week ago we sold a fellow a new airplane and arranged for his support for him to operate. Last Friday he came back for his second new airplane and he was able to expect him to come for his third new airplane soon.

For every student we lose to such a competitor we get two new ones either as a result of the good will created or because they heard of us through our dealing with the new operator.

In other words, the more operators there are the more business there is for each one. I believe this reasoning will increase because the very nature of airports limits their number. When people in general really begin to fly there will be no more airports to accommodate them. —*Arthur H. Hawkins, President, Bonnet Air Service, Central Jersey Airport, Hightstown, N. J.*

Should be discouraged

I did not at all in accord with the suggestion about how to proceed that newly licensed students be encouraged and allowed to open up when and where they will and start selling airplanes in competition with established schools. "We have a lot of it throughout the country today and it is actually becoming a menace to the welfare of aviation," because of the sometimes unmet competition, but because of the thrill-seeking youngsters who have learned to fly for fun and it is all too often allowed.

Question 19

(I would like to be published in November)

WHAT method do you employ to insure acquisition of student interest while the time spent upon between ground and air portions? How do you compute the necessary theory between the ground and the air and the training speed of the student? Do you hold a monthly requirement to ensure plane safety if they are back down for mechanical trouble?

with the wrong sort of enthusiasm. I believe that a student who has given the proper license, and whom the established operator knows to be anticipating a venture of his own is attempting to start a school, should be discouraged from the idea with a serious heart-to-heart talk about the necessary experience needed by the instructor and about the duties of a school to the public.

It is my opinion that the Department of Commerce should make the delivery of the newly licensed student attempting to instruct, and should make it compulsory for him to have a minimum of at least 500 hours before he does.

A flying school should be a very serious business enterprise, established by a capable instructor or the object of the usual early graduated young pilot, for as a rule, the young pilot has no capital himself, and is plunged into the security of domestic business, is inclined to cut prices, reduce to bad business method, and to allow any flying contrary not only to the principles of good business but to the progress of aviation.

I therefore believe that it is not good business for the young pilot to attempt to do business in aviation instruction, or to sell him a ship for that purpose, for in the long run it really acts as a boomerang. —*Earl B. Foster, Jr., Al American Airport, Miami, Fla.*

"Ock" student's ships

THIS young student who wants to go into business for himself has not been much of a problem with us. We believe the prospective student fully cognizant of the fact that his flight training should be under the guidance of experienced instructors and will not be able to purchase success who has just recently obtained his transport license. It is possible for the young, new operator to do some rental business, but his participation in the management of such a business and the tendency of students to point to purchase other operators who have an established reputation will not enable him to offer services competitively. We take care of this problem by trying to sell the student a ship, and it is better to make some money and to use it "back" at for him collecting a valuable education on the ground before breaking him with customers and handling the transactions. —*George A. Vassallo, Manager, Southern Flying Service, Inc., Southern Hills Airport, Bellinghame, New Jersey.*

LIGHTER and STRONGER- FASTER and SAFER . . .

thanks to U-S-S STAINLESS STEEL

IT'S U-S-S Stainless Steel that makes the Fleetwing "Sea Bird" amphibian lighter and at the same time stronger, faster and at the same time safer. The explanation? Just two simple facts . . .

Of all metals available for airplane construction, stainless steel has by far the greatest strength-to-weight ratio. And of these metals, only stainless steel is truly corrosion-resistant—no truly corrosion-resistant that corrodes or "chips" are never needed, that means can never dent its brilliant surface.

Example: Since there can be no

loss of metal by corrosion, the danger is free to use thinner sections extending farther from their central axis . . . and these sections can be bent. Result: Light weight sections of tremendous strength.

Important, too, is the "showed" process of stainless steel construction. Hot, hard and strong, stainless steel is made virtually one strong homogeneous metal unit. And with no even heads to interrupt the structure, also friction drops to a minimum.

Unquestionably, stainless steel is an ideal metal for airplane construction. To airplane designers and operators, it offers inviting, challenging opportunities to build new planes lighter and stronger, faster and safer.

For further information on the Fleetwing "Sea Bird" amphibian, write to Fleetwing, Inc., 2001 E. 1st Ave., Philadelphia, Pa. or the "Stainless Steel" section, write to U-S-S Stainless Steel, 1000 N. 10th St., Philadelphia, Pa. or the properties and applications of U-S-S Stainless Steel, write to the nearest office.

S-43... Queen of Air Transports

State Officials Convene

(Continued from page 20)

The conventional plans of the future meet temper with suitable plans and direct control given. In limited 35-40-jet air-rafts have been made in given with ordinary engines. The practice of saving money in the case for landing may be followed in the future.

Aerobically engines for planes are still slow and lacking. The particular applications tried so far were slightly disappointing but a new Ford Model D engine, for which the price cost \$190 less good.

No "Darius Green" underwriting

Insurance rates for them are not the result of a "Darius Green" method of underwriting, according to J. E. Hawkins, of the Transair, Inc. and other companies has a special committee of airlines drawing still badly to its advantage.

The fundamental principles of insurance require that each policyholder pay a rate of premium sufficient to pay his share of the claims among a group of similar policyholders.

It has been found, for example, that in airport and cross country line flying the combined death rate is about eight pilots for every 100,000 hours flown. Pilots engaged in these classes of aviation, averaging 300 hours per year, must contribute \$24 a year for each \$1,000 covered to pay for the death claims arising from air accidents.

There is a high spot in the mortality rate for transport and military pilots with 200-300 solo hours probably due to over-confidence.

The odds are 25,000-1 against a passenger's being killed on a scheduled transport trip. The death rate on the average air transport trip is about 15 passengers per 100,000 passenger hours. In a group of policyholders who travel 100 hours each a year on the airlines, the death claim cost on average of air transport accidents to the insurance company averages \$130 a year for each \$1,000 of insurance. Since the average premium per \$1,000 is about \$38 and may go as low as \$25 for short term insurance, some companies feel that the additional \$10 should be added to the premium. This does not imply that the risk of air travel is good but that it is above the average.

World Aeronautics

Drawing a world picture of aeronautics progress and reflecting on the work in airport and airlines development and direct control of the Bureau of Air Commerce, Col. J. M. Johnson, Assistant Secretary of Commerce, addressed delegates at the Chicago Airports Col. Johnson concluded his remarks with a definition of the duties and re-

sponsibilities of State and Federal aviation officials. He told of the major program, now underway, to revise the regulations of the Air Commerce Bureau, to adapt them to the expansion of ac-

tivities expected in the next decade. The most important of the new regulations will be evolved among a select group of interested persons for aviation and commerce.

New Volumes

New arrivals in the office library

AIRPLANE DESIGN PERFORMANCE, by Edward F. Warner, McGraw-Hill Publishing Company, New York and London, 1946, 651 pages, 419 illustrations, \$1

MANY a man who stands back in the field of airplane design today can see aeronautical wisdom both on Werner's *Aerodynamics of Airplane Design* (1937). Safe to say, also, that no airplane of the last ten or seven years came into being without frequent floundering through the pages of this classic work. But more better than the author realized that the period 1937-1940 had witnessed sweeping changes in many technological concepts, and that the original volume had "taken badly out of step with the art." Early in 1945, therefore, he embarked on the tremendous task of revision.

The job proved, however, to be much more than that mere revision. Aeronautical research had yielded so many new facts and modern operating techniques had opened up so many new applications, that an entirely new plan of presentation had to be adopted, the first had to be almost completely rewritten, and practically all of the original charts (where they could be used at all) had to be redrawn. The common idea that an author of a text book can get a new edition of a previous work "with the greatest of ease" really did not apply to this case. It is substantially a new job from start to finish.

And the result is well worth the effort. Not only is the subject matter beyond measure in the usual University tradition for accuracy and completeness, but the readability has been tremendously improved. The reader work covered with it is the most in his formal education of the classroom and lecture hall.

The style of the present volume, however, shows the influence of the author's later experience as an editor, and of his close contact in recent years with industry people. It is noticeably simpler, almost conversational in places—all of which helps carry the reader over the rough spots.

Again, as in the first edition, the author's objective has been to confine the theoretical treatment to "very modern knowledge of such in the minimum of volume." Long demonstrations of mathematical theory have been sacrificed in

favor of presenting fact results in simplified form and in relating them to the practical experience of the reader.

Where it was possible to cover the entire field of developments in one volume in 1937, the great mass of data that has accumulated in the interim has made it necessary to divide the subject in 1946. The present volume, therefore, deals only with airplane performance and with the basic aerodynamic laws and phenomena that control it. A second volume on stability and control is promised for the near future.

★
AIRPLANE AND ENGINE MAINTENANCE, by THE AMERICAN MAINTENANCE, by Daniel J. Wilson and H. Edward Engquist, Pitman Publishing Corporation, New York and London, 1946, 493 pages, bound covers, \$2

OVER of the most practical books we have seen for a long time. It was designed for a specific purpose, to give the student and the mechanic at work in the field prompt information about his job in a clear and understandable manner. The authors set to be connoisseurs upon the degree to which they have stuck to their intention. Two other books of this nature are distinguished by wandering off into theoretical fields that confuse rather than clarify. Frequent illustrations (photographs and diagrams) help the student remember what it is all about.

Four main subjects are treated: Aircraft wood work, Aircraft metal work, Aircraft fabric and covering, Rigging, landing and maintenance. The illustrations have drawn heavily on equipment manufacturers for details, but have supplemented and complemented the material out of their own experience in engineering, spending and in student maintenance.

Nevertheless the first volume may be subject to some criticism. A considerable effort has already been made to keep the price of the book down, but in view of the fact that it would be difficult to find a substitute in the shop, we are afraid that the binding and the covers will not be able to take it. We hope this future prototype will be made more suitably put together even if the price must be advanced slightly. It would be worth it.

PIONEER CLIMB INDICATOR

(Self-Contained)

Type 1042*

Type 1045*

The latest design of the Climb Indicator (selfless) is presented in two versions. The complete instrument, contained in a standard A. N. case, 2½ inches deep, requires no external reservoir • Type 1042*, graduated in intervals of 100 feet per minute, makes possible extremely close reading in the lower half of the scale • Type 1045* has a standard scale with even graduations of 200 feet per minute for the range of 2000 feet • Both instruments are thoroughly compensated for temperature and altitude changes, and a unique device holds the humidity within the case constant. These combined features make for an extremely sensitive and accurate instrument that has won world-wide approval.

the cooling water are mounted high in the engine. When necessary they can be supplied from the water storage tank in the hull by means of a semi-automatic hand pump.

Tubular radiators for cooling the lubricating oil are hung in the air stream under the wing outboard from the fuselage. For summer operations in the tropics, additional radiation for the cooling water has been provided by means of flat-type radiators suspended below the wing surfaces outboard from the tubular oil radiators described above.

Of particular interest are the power plants themselves, the Jumo 2. Development of heavy oil engines of this type was begun by the Junkers Co. way as far back as 1926 when Professor Junkers built the first experimental area ducted for test bench purposes only but on the same principle as the present Jumo 2. After a long research the first aircraft diesel engine was the Jumo 4 of 700 hp which was fitted to several Junkers F-24 aircraft for experimental work. These engines proved so successful that Junkers installed them in the four-engine transports of their fleet, the Junkers G-36. A somewhat smaller engine which embodied all the experience gained with the Jumo 4 was built, the present Jumo 2.

These engines are of the compression spark type, having a special oil and developing 386 hp each. The arrangement is an cylinders in line, but each cylinder is double-acting, containing two pistons each of which gives a separate revolution. The two revolutions are geared to a common propeller shaft.

These engines operate on the well known diesel principle in which air is

compressed in the cylinders and fuel is injected into the heated air at the proper instant. There are, therefore, no ignition systems, no carburetors and no valves of the type used in other aircraft engines. The fuel consumption of these engines is extremely low. [Jumo's "All the World's Airways" 1937] gives a fuel consumption of 344 to 375 lb per hp at normal output; and 275 to 290 lb per hp at maximum output.—Ed.]

So much for the airplanes and their engines. Another interesting piece of mechanical equipment on the Atlantic operation is the catapult as installed on the *Schlesienland*. It is essentially of the same type as originally conceived on the *U-36* which has with improvements. Where the catapult equipment on the *U-36* was a simple forward, however, on the *Schlesienland* it is aft. The lifting hoist are launched from the stern of the ship. During catapult operations, rough weather is kept on the seaborne to maintain the heading into the wind at all times. As can be seen in some of the accompanying photographs, the catapult is mounted on the port side of the ship with the crane and the truck for handling a spare aircraft to starboard. The reel and arrangement for handling the net agent is located at the stern below the catapult.

The catapult proper consists of two long steel rods (about 150 ft in the clear) on which is mounted a cart, or rather a sled. The latter is not mounted on wheels but slides directly on the top of the rods.

The cart is pulled along the catapult by two flexible steel cables each of which is about 2 in. in diameter. They are kept well lubricated, both for protection against corrosion and for flexibility.

The cables pass over a large pulley near the discharge end of the catapult and from thence under the structure to the operating cylinders located about the corner of the foremast. Thence the cables pass back and forth over a system of sheaves arranged very much like the ordinary block and tackle. This set of sheaves is stationary and the cables are mounted on a slide which is free to move in the piston of a large air cylinder. By forcing the two sets of pistons apart by the action of the air cylinder the relative motion of the pistons is transmitted to that of every foot of travel of the piston, 6 ft. of travel on the catapult carriage is obtained.

Compressed air for operating the launching cylinder is stored in large tanks immediately below the cylinders. Pressures between 1,200 and 1,400 lb per sq in. are employed. Two off-loads is used according to the speed of surface winds by varying the pressure of the compressed air.

With the plane on the carriage on the take-off position the two engines are started up and are finally run up to full throttle. After the crew have gotten themselves properly located in their places, the pilot pushes a small button under his right thumb on the steering wheel which flashes a red light at the firing station. The catapult engine then throws a lever against the valve connecting the compressed air container and the cylinder, the piston forces the two sets of pistons apart, and the carriage is accelerated along the catapult. It is accelerated from a standstill in about 10 to 15 seconds to a speed of about 100 mph. By the time the catapult is about 100 ft from the ship, it is able to climb directly after leaving the catapult. There is no loss of altitude. Actually the least leaves the carriage somewhat before the end of the catapult is reached. Thus the problem is to stop the carriage. This requires considerable braking. The aircraft about to be launched is decelerated from 80 mph to a standstill in about 15 ft. Two sets of brakes are used. The first consists of a knife-edge rest of steel mounted on the underpart of the carriage which slides between pairs of stationary steel shoes under the end of the track. The steel plates are pressed together automatically by air cylinders. The pressure in the brake cylinders is the same as that used for the launching cylinder. The other braking action comes from the launch cable. Since the pulley at the discharge end of the catapult is not at the extreme end, the carriage overruns it and the cables then act in a reverse direction tending to stop it. During this part of the cycle the compressed air cylinder acts as a sort of shock absorber to cushion the carriage with maximum shock.

Although the accelerations during catapulting may run as high as 2 to 2½ g, there are no noticeable ill effects on the crew as in many air sea launches a day.

Junkers F-24 aircraft

At Last!

A NOCORONA® SPARK PLUG

**CHAMPION NOCORONA® AIRCRAFT
SPARK PLUGS FIRST TO ACHIEVE
LONG SOUGHT RESULT**

It was only recently determined that corrosion occurs within nickel spark plugs as was one of the causes of misfiring, hard starting and rough engine performance in aviation motors. Likewise, it was established that corrosion was present in positively oil mist sealed spark plugs of conventional design.

Champion has just had the great satisfaction of developing a corrosion seal at the same time on absolutely gas-tight or compression-proof nickel sealed spark plug. In both the shielded and unshielded types. These two long sought advantages are available only in Champion NOCORONA Spark Plugs and definitely better than standards of engine performance and dependability of all aircraft engines.

The aircraft industry only recently realized the importance of corrosion seal plugs in aircraft engines. Champion is proud to announce that their new NOCORONA Spark Plugs meet this most important.

Tests substantiate that Champion NOCORONA Spark Plugs do smooth and performance, eliminate misfiring and make starting much easier. Install a set in your ship and see for yourself what Champion will do for your engine. Available in the latest radio shielded or unshielded type.

Centerline to U. S. Army Air Corps.

Hangar Jack

Hydraulic equipment aids the servicing of Chicago and Southern planes

HYDRAULIC hoists or lifts of the type commonly found in automobile servicing stations should find a number of applications around airports and in airline maintenance shops. The simple type of hydraulic elevator might be installed at loading spaces to facilitate loading of mail and cargo into airplanes to replace the slow and awkward scribbler method now in general use. One installation, the Corbin Pressurized Machinery Company has for

Group of Corbin and Jenkins hydraulic hoist showing the way in the up position with wheel extended.

The hoist hoists are removable when not in use so that the floor can be kept absolutely clear of obstructions.

The ship into its lowered position, thus making room for the engine without any further delay.

The Maintenance Notebook

Short Cuts from the Overhaul Shops

and also so that the ship would not have to be too accurately placed in order to use the jacks. The rotatable wheels on the top of the jacks also allows for fore and aft movement of the ship when raising and lowering it.

Propeller Straightener

Device developed for straightening bent aluminum propeller blades by the means of a small strap shap

It is no easy thing to straighten bent aluminum propeller blades by the means of a small strap shap. To provide something for the small shop owner, Northwest Air Service, Inc. (Seattle, Washington) has developed a tool that will turn out a very satisfactory job. It will not only straighten damaged blades, but may be used for repairing Corbin-Rent or other similar propellers. As shown in the photograph, it consists of two large wheels which may be rotated, one with respect to the other, by means of a lever and a gear and pinion. One of the wheels carries a heavy frame in which the pinion is mounted, the other carries the gear itself. The tooth ratio is one to one, and with the leverage furnished by the lever handle, one man can apply sufficient pressure to straighten any standard aluminum alloy blade. Straightening operations are begun at the point nearest the hub and proceed outward progressively toward the tip. The "width" of the change is 6 in. so that the work is done at 6 in. station along the blade. The straightener is designed to be used with the propeller mounted on the jack stand. Northwest Air Service, Inc. is putting a number of these tools into production and they are now conveniently available.

Northwest's popular straightener

In the observer's compartment is James Hendland, TWA's development engineer. Below him will be his array of 36 instruments to tell an accurate story of the functioning of the engine. Engine performance—operation of supercharging equipment, fuel consumption, speed differential, temperature—will be the primary concern of the experimenter.

To help accurate recording, a camera is suspended in the rear of the observer's compartment. With every 1,000 ft. gain in altitude, two lights will be turned on the instrument panel, and a picture of the instrument group taken.

Pilot and observer will be enabled to withstand the rigors of cold and low pressure by the use of heaters and breathing tubes for oxygen supply. The special clothing will be worn. Comforter's seating is provided with a special emergency brace which also holds the oxygen tube, allowing him to keep in communication with the ground by radio and take necessary oxygen at the same time, leaving his hands free for flight.

Also engaged in a high altitude research program is Britain's Royal Air Force, through the Royal Aircraft Establishment at Farnborough. On Sept. 29, in the first phase of the program, Squadron Leader P. R. D. Swan captured the world's supreme altitude record from the President Georges Dervé, who himself had broken a 14-day record that a month earlier, Swan's flight, just to be homologated by the F.A.I., was 40,067 ft.

The step by step, known as Bristol 138, was ordered from the Bristol Aeroplane Co. In November 1933, and was the result of stated specifications on the part of the Air Ministry and skilled execution by Bristol engineers. It is a low-wing, rubbered, monoplane, constructed for lightness, weighs of wood spans is 66 ft., length, 44 ft. Wing loading is very light, 13.5 lb./sq. ft. Total empty weight is 4,391 lb.

The Bristol Pegasus engine, P.R. VI 8, is fitted with a two-stage supercharger, and carries a four-bladed wooden propeller 12 ft. 9 in. in diameter. The engine was designed to deliver 525 hp at 10,000 ft., and 457 hp at 43,000 ft.

The pilot's special equipment consisted of a rubberized-lake pressure suit, helmet on two sections and fitted with a mask of the same material, with a later

revised double window. Oxygen supply is through a closed circuit, with carbon dioxide and moisture content removed from the used breath before it is returned to circulation.

A second high altitude plane, similar to the Bristol 138, has been contracted, but it will be powered with a water-cooled Rolls Royce Kestrel. The Pegasus is an air-cooled piston. Further flights will be made "in due course."

New York Show

Three months before opening, 40 space applications reported

Attendance at will be three months before the National Aviation Show (Jan. 29-Feb. 6) will open its doors to the public in Grand Central Palace, New York, managing director Gustave A. Purvies has reported that more than 40 prospective exhibitors have reserved space. It will be the first aircraft show to be held in New York since 1930—seven years.

Purvies has estimated that of the 250,000 expected to attend, "at least 10,000 are potential new cash customers for air travel, for instruction, for planes and accessories."

Johannesburg Race

Only one entry is nine finishes 6,150-mile grid

Last May L. W. Selldemeyer, wealthy South African sportsman, offered \$50,000 for an all-British air race between England and South Africa. The race was to be divided into eight and handicap contests. First prize at the speed event: \$20,000. Handicap prize ranged from a first of \$15,000 to a fourth of \$2,500.

The course was laid out from Portsmouth, England, to Johannesburg, with a starting point at Harlowe, Yorkshire, and a landing point at Orie.

Nine planes took off from Portsmouth in the dawn of Sept. 29. On Oct. 1 Charles W. A. Jones—captain of the Mollisonian, London-Melbourne race in 1934—and Gila Gullone were also German Airport, Johannesburg. They had driven their open-toppered Ford and Vega (all) over the 6,150-mile course at 52 hours 56 minutes, and won the only entry to finish of all. The other eight ships were scattered from Rajasthan, Gurney, to Gend, South Africa, either downed by bad weather, broken or crashed. Two captains—Capt. Rose Penley and A. H. Munn, flying an Airspeed Envoy with Kenneth Waller and C. D. Proctor—were killed in a take-off crash at Orie, on Lake Tanganyika.

Industry Expands

K. L. M. Douglas, Lockheed looking, Fairchild recognizes

ALCON AIRCRAFT CORPORATION has been incorporated at Lansing, Mich., with an authorized capital of \$300,000 shares of \$1 per value common stock. The company has purchased domestic manufacturing and sales rights for the Arrow Spans, V-4, along with machinery first manufacturing, and has secured rights in the Arrow Aircraft & Motor Company's \$300,000 plant at Lansing.

Oct. 14 Robert C. Company of New York, N. Y., offered 250,000 shares of the stock at \$1 per share. Arrow expects to inaugurate a production schedule of four planes a day. Offices of the company are 300 N. W. Blvd., New York, George Woods, vice-president; E. F. Woods, executive vice-president; and John G. Aldrich, secretary-treasurer. Consulting engineer is D. E. Anderson, chief engineer at the Tulsa Aircraft & Brass Company, of Tulsa.

The Beach Aircraft Corporation is planning a stock issue to be approximately \$400,000. Walter H. Beach, the company's president, and that part of the proceeds will be used to purchase from the Cessna-Wright Airplane Com-

TO RIGID AIR LINE SCHEDULE

Roebling has pioneered in the development of Wire Aircraft Products

TODAY and since the inception of the aviation industry, Roebling keeps step with an industry whose constant watchword has been Progress. Most principal plane builders now turn to Roebling for the solution of their wire and cable problems. And in the years to come Roebling will continue to pioneer in the improvement of wire aircraft products.

Roebling Wire Aircraft Products include—Tinned Aircraft Wire, 19-gauge Aircraft Strand, Tinned or Galvanized Aircraft Cord (6 x 7, 7 x 7, 7 x 13), Tinned and Galvanized Ferrous and Nonferrous; Serving and Lashing Wire; Control Strand and Cable; Electrical Power and Lighting Cable; Gas and Electric Welding Wire.

BRITAIN'S PROGRAM

(Type) P.R. VI 8, which carries Hendland, the Bristol 138.

SPIRIT?

• Up in Canada the flyers sometimes call gliders "spirits." This makes as fast good, planes run through our head like—the spirit of aviation...the spirit of a motor...the spirit of power... To us, on the south side of the border, it may seem odd to endow any ordinary glider with the fighting qualities of a word such as Spirit! But for Eby! It's just right! Eby! General Corporation, Chrysler Building, New York City.

plant the manufacturing plant at Wichita, Kan., which is now leased.

KLM (Royal Dutch Airlines) has purchased eight Douglas DC-8s from the Douglas Aircraft Co., Santa Monica, Cal. The first of the order left Santa Monica Sept. 24 for New York. The other seven will be delivered next spring.

La Cof-O Aircraft & Tool Corporation, Denver, has announced the appointment of the Herberts Manufacturing Co., Ltd., Los Angeles, to conduct sales representation in southern California.

Fairchild Aviation Corporation stockholders were scheduled to vote Nov. 2 on a proposed split-up of Fairchild subsidiaries. Under the reorganization plan, Fairchild Aviation would retain full ownership of the Fairchild Aerial Camera Corporation, which manufactures aerial cameras and other products; aircraft restaurants in Woodside, Long Island, and its interest in Fairchild Aerial Surveys, Inc. The airplane and engine manufacturing subsidiaries, Fairchild Aircraft Corp., of Elgin, Ill., and the Raper Engineering Corp., located at Farmingdale, Long Island, along with the company's interest in Fairchild Aircraft, Ltd., of Canada, would be transferred to a new company, Fairchild Engine and Airplane Corporation.

The plan calls for the distribution to present stockholders of shares of the new company on a share-for-share basis. One feature of the plan calls for cancellation of \$30,000 of 6 per cent Fairchild Aviation Corp. notes, for \$445,000 of which holders will accept 32,465 shares in the present corporation. For the balance, holders will accept 3,764 shares of \$100 par, one per one convertible preferred stock of the new Fairchild Engine & Airplane Corp. These shares on this issue will not be payable or convertible to stock until January, 1959. Sherman M. Fairchild will continue as president and chairman of the board of Fairchild Aviation, and will occupy the same positions in the new company.

Robert E. Green, president of Lockheed Aircraft, has announced that the September order backlog—\$1,810,000—was the largest in the company's history. A new transport, similar in design to the Electra, is on the drawing boards of Lockheed engineers at Burbank. It is known as the "Super-Electra," and is designed for fourteen passengers. Already orders are reported "from a large airline."

Capital stock of the Givens L. Martin Co. has been increased from \$5,000,000 to \$4,000,000, consisting of 1,500,000 shares of common stock with a par value of \$1.

Nissan Manufacturing Co. has reported a \$150,000 export order backlog, with recent orders from Germany and Japan. A representative statement has

been filed covering issuance of 70,000 shares of stock with a \$5 par value. They will be offered at \$3.75 a share, the proceeds to be used for subsidiary purposes and repayment.

Sept. 30, Severely delivered the last 35 basic trainers under its first Army Air Corps contract, and will concentrate on contracts for 85 private.

With plans for a production schedule of one ship a month, Spartan Aircraft Co., through vice-president and general manager Edward W. Hadden, has issued a call for 50 additional men.

The Philippine Constabulary Air Force has placed an order for ten training planes manufactured by the Stinson Aircraft Company, Wichita, Kan. There will be Model 72-13 primary trainers, powered with Lycoming R-680-C1 engines at 225 hp. They are similar to the three delivered to the Philippine last spring. The other three, Model 76-20L, are equipped as advanced training and supplementary types. They will be covered with 250 hp Pratt & Whitney Wasp Juniors, Series T13.

Tokerech Aircraft Corp. has been incorporated at Atlanta, Ga., for the production of C. G. Taylor's new light plane. Incorporation is for \$54,000 (400 shares of \$50 preferred stock and 1,800 shares of no-par common with a declared value of \$5). Presided will be C. G. Taylor, vice-president, Alex Robertson, secretary, S. L. Geiger, and treasurer, George O'Brien. Five shares are authorized.

The Walsh Aircraft Company, which recently moved to the Bendix Municipal Airport, South Bend, Ind., has said two planes, one to Larry Mahoney, Anderson, and the other to G. F. Koclar, Jr. of Mankato, Ill. Before moving the plant will be moved to the old South Bend Walsh Co. plant, where work will start on an order for 50 planes for F. W. Brown, of Fowler, Ind.

Engineers and production men met in Los Angeles Oct. 15, 16, and 17 for the first Aircraft Production Meeting sponsored by the Society of Automotive Engineers. Main presentation in the industry discussed, in fourteen papers, problems impeding the industry's rapid growth. Further details of the

Traffic

Latest available statistics from the Bureau of Air Commerce and the Post Office Department—Domestic airlines only

statistics will appear in Aviation's December issue.

Taylor "Cats" have been approved by the Bureau of Air Commerce with a 40 hp engine installation, instead of the 37 hp used heretofore. New engines will be the Continental A-48-A.

The Department of Commerce announced Oct. 1 that summarized reports for the first eight months of this year were valued at about \$14,500,000. This was equal to the total value of exports for all of 1953, and an increase of 56 per cent over last year's first eight months. Commerce said that the total of the year may set a record value of \$20,000,000 of international exports. The previous high was in 1954, when foreign purchases bought \$17,411,000 worth of American aircraft, engines and accessories.

FORMICA PULLEYS AND FAIRLEAD BUSHINGS FOR AIRPLANES

A VERY large percentage of the airplanes, both government and commercial, turned out by American manufacturers this year are equipped with Formica control pulleys and fairlead bushings.

The weight of Formica pulleys is approximately half that of the lightest metal pulleys for the same purpose. They are being constantly tested under the Army and Navy specifications for inspection of pulleys, covering run-in tolerances, static load, loading, fringe shear and resistance to fatigue.

Closest contact with Army and Navy aircraft engineers keeps them up-to-date.

Let us quote on your requirements.

THE FORMICA INSULATION CO.
4618 Spring Grove Ave., Cincinnati, Ohio

Routes, Equipment, Rates

Electras for Boston-Maine: United issues stock; Mexican service on Braniff; American orders DC-3s; air freight service by TWA.

It was expected that air carrier business, Chicago & Southern Air Lines control, was in full bloom. The first nine months of this year saw an increase of 75 per cent in the number of passengers carried over the same period in 1933, with 4,570 passengers from January to October. In the same period, air mail payloads increased 25 per cent, express payloads 50 per cent.

United's Lockheed Electras were scheduled to go into service on Boston-Maine-Central Maine route, beginning Oct. 15. The Boston to Burlington, Vt., schedule will be cut from two hours and fifteen minutes to one hour and 11 minutes from Boston to Bangor, Me., from two hours and twenty minutes to one hour and thirty-five minutes. Actual flying time will be even less because these routes include five alternate stops at ports of call.

Pennsylvania Airlines, operating between Washington and Milwaukee, showed gains in passenger, mail, and express traffic ranging from 24 to 395 per cent for the first eight months of this year. Air express was first, with 395 per cent, while air mail provided only to the Detroit-Milwaukee portion of the system) doubled 128 per cent. The line carried 27,069 passengers for the first eight months—24 per cent more than the same period last year.

September 23 applications of United Air Lines indicated increase in the number of shares in 1,200,000, with a \$1 per value, to \$200,000, with the same per value. They will be offered to stockholders at \$11 a share, on the basis of one new share for each three now held.

The offering will net the company about \$1,000,000, which will be used to pay for the twenty Douglas DC-3s now on order, and to improve ground facilities for the new ships' use.

For a third crew member, Eastern Air Lines has turned to men. On Dec. 1, according to E. V. Richenshaver, general manager, "Night steward" will be placed aboard every plane. Their duties will be similar to those of the hostesses used on some other lines. According to the announcement it will be their policy to be "particularly attentive when needed, and, almost available at other times." Qualifications will include height of 5 ft. 4 in. to 5 ft. 6 in., weight of 125 lb. to 150 lb., and age ranging from

23 to 25. Full-time air goes to 40 miles. On Oct. 1 Douglas DC-3s replaced the 10-passenger Lockheed Electras on Eastern's 9th to Chicago-Maine run. The change is attributed to increase in demands for space on the Chicago wire.

A 750-mile foreign extension is under construction by Braniff Airways, to run from Brownsville, Tex., by way of Monterrey in Mexico City. This will provide direct connections from Chicago to the Mexican capital. The greatest connection at Brownsville with Pan American, serving Mexico City and Central America by way of Tampico, will be continued. Braniff's schedule will be arranged for a different time of day.

The work of equipping and loading of the new airway is under the direction of Don C. Withledge, General Operations Manager, who left Dallas last 3 is a specialty equipped car to carry the livestock. The job entails construction of an airport at Brownsville and other International landing fields, setting up a field transportation system, a complete radio system, and weather service.

14-passenger planes (previously DC-3s, or the new Super-Electras) will be used. Another order for Douglas DC-3s. Flagships has been announced by C. E. Smith, president of American Airlines. Prior to \$100,000 each. This latest order for five five-engine, American's companies up to 25. Thirteen have been delivered, of which eight are DSTs (stoppers). All others will be 21-passenger day planes.

The ICC has postponed from Sept. 15 to Oct. 27 the hearing on Eastern's complaint that American was violating the air mail act by carrying passenger service between Newark and Washington.

Swapping reductions in passenger fares were announced last September by Transcontinental & Western Air. They will go into effect Nov. 1 at special winter rates. By some swap (air transportation) purchase, in \$300 blocks, the fare between New York and Chicago is cut to \$13.96, only 21 cents more than old plan Pullman. The old fare was \$14.96. Winter rates for the transportation run are reduced from \$150 to \$118.96.

TWA's long-pending application before the ICC for all-line service between Albuquerque and San Francisco has been reported by ICC members George A. Kayser and Lucian Jacobson. They held that the service was required by public convenience and necessity; that it would not tend to increase the cost of carrying mail, but recommended that the Commission decide the application because service would, under the act and law of 1924, be filed in that it "would be competitive in some way with the services upon the route of regular air mail carriers."

Express-only service was prohibited between New York and Chicago by TWA Oct. 19. Schedules called for midnight-to-dawn service in each direction, using Ford trimotors with \$500 fly payload capacity. Rates are reduced from regular express charges as much as 37 per cent. (\$2 per 100 lb. New York-Chicago as against \$5 per 100 lb. regular air express).

The Bureau of Air Commerce has announced the perfection of a radio type-writer machine, which has been in operation between Washington, D. C., and Baltimore, Md., for a year and a half. It offers a means of transmitting

TO ELIMINATE STATIC

from radio or a new United Air Lines has perfected this static-free antenna for reception of direction radio beams. It is installed in the nose of the ship.

and receiving eye-witness accounts without the use of land wires, and may be used with any number of receiving machines simultaneously.

It is proposed to install the service on the new army which has been under construction for the past year between Washington and Nashville, Tenn. Cost is estimated at about \$350,000, and the Bureau expects to save that amount in reduced transmission costs in a little more than three years. The apparatus developed for use aboard plants weighs only eight pounds.

Accident Report

Bureau unable to explain Chicago & Southern crash

A Bureau of Air Commerce report on the crash of the Chicago & Southern Air Line plane at St. Louis last Aug. 1 found no more informative cause than that the pilot "was making a turn at an extremely low altitude, low enough, however, at which the wing of the airplane unintentionally contacted the ground."

The pilot had turned back toward the field after "fast cuts" that two minutes in the air, though why he had done so was characterized in the Bureau report as an "unexplainable factor" in the accident. Experts were apparently questioning himself, and at cruising speed or slow. The Bureau holds that there is "insufficient evidence to substantiate any of 'hazard theories'" in the incident's cause that had been suggested.

Export Grummans

Manufacturing rights sold to Canadian Car & Foundry

Early in October an agreement was reached between the Grumman Aircraft Engineering Corporation and the Canadian Car & Foundry Co., Ltd., of Montreal, giving the Canadian company design and manufacturing rights to the

Grumman FV1 two-seater fighter. The ship will also be developed by Canadian Car & Foundry as an advanced trainer by installation of a 440 hp. engine. Grumman has interest in lighter versions, but only new engine mounts and cowling for installation of a 750 hp. or 1,000 hp. engine—a job that can be done at any maintenance base. No structural changes are involved. Top speed as a trainer is 155 mph. With a 750 hp. Cyclone, the top is 221 mph with full military load.

Late in December, Lt. Col. Howard F. Klein, the company's chief pilot and technical adviser, will take one of the ships, equipped as a two-seater fighter, on a three-month sales tour of Central and South America. The tour will start from Greenville, Tex., and then work down the Central American peninsula and the west coast of South America, then across to Buenos Aires and Montevideo. From there the route will go north to Rio de Janeiro.

Canadian Car & Foundry, established 26 years ago, is headed by Wilson W. Ruffer, a native of Detroit, O., and former vice-president of the American Car & Foundry Co. In charge of aircraft manufacturing operations will be Vice-president J. A. Perry. The plant has a capacity of fifteen planes a week.

Navy Opens Bids

For patrol, scouting launches; Bell gets Coast Guard order

The Navy Bureau of Supplies and Accounts took three more steps in the Naval Aircraft procurement program last month. On Oct. 3, bids were opened for the construction of 66 flying boat patrol planes (VP-1). Three bidders were considered, \$6,274,073, Hughes, \$7,008,120, and Douglas, \$5,540,877. Bids for the construction of scouting launches (VS-1) were opened Oct. 26. Only bidder was Chance Vought Division of United Aircraft Corp., which bid \$490,484 for 25, or \$19,619 for 40. The planes will be assigned to the Naval Reserve Aviation Base and to the fleet.

AVIATION November, 1935

Oct. 14 the Treasury announced that an order for six Coast Guard flying boats had been awarded to the Hull Aircraft Company, of Boston, Pa. The boats are biplanes, and will cost \$709,852. They will be used for scouting and rescue work.

Swede to Ireland

Ripkval leads in test in attempt of N. Y.-Stockholm flight

Larsen here flew to choose the north Atlantic route in the quest for glory was Kurt Ripkval, a young Swedish commercial pilot who wanted to fly to Stockholm. The flight was originally scheduled for Ripkval and a companion, the famous Eva von Bismarck. But on Oct. 6, after weeks of delay, Ripkval took off from Floyd Bennett Field, Brooklyn, leaving the Bismarck family on the ground.

Expensive trouble brought him down where nearly within sight of the Irish coast. The French trawler *Labrousse* picked him up, and landed him at Victoria. His plane was abandoned at sea.

The trip Ireland-Australia and England-New Zealand records were again broken last month—by a woman. Jean Harlow, New Zealand girl flyer who last year made a solo powered crossing of the South Atlantic, took off from Lympne Airport, England, on Oct. 5. She landed at Port Darwin, Australia, 11 days, 21 hours, three minutes later. From there she flew to Sydney, where was to be the starting point of a 1,130 mile flight across the Torres Sea to Auckland, New Zealand. She made the trip in two hours and a half, flying in spite of the Australian Federal Aviation Board's objection to crossings in single-engine ships. Her first time England was 11 days, 37 minutes.

Financial

Profits for Douglas, Lockheed, Beech; American Airlines losses

A net profit of \$227,664 for the nine months ended Aug. 31 was reported by Douglas Aircraft Co. This is equal to 26 cents a share. It compares with a \$1,802,746 profit for the first nine months of 1935.

Lockheed profits for the first nine months of 1935 came to \$40,215, against a \$232,094 profit for the same period in 1934.

For the period from Jan. 1 to Sept. 30, at which time it was succeeded by Beech Aircraft Corporation, the Beech Aircraft Co. reported a net income of \$11,080. The last year of 1935 showed a net of \$7,056.

A net loss of \$438,332 for the six months period ended June 30 was reported by American Airlines.

Striking Power—DEFENSIVE POWER BOTH INCREASED

Today's Martin Bombers stand out in vivid contrast—even with those of a year or two ago—increased reliability, increased striking power, speeds up to 240 miles per hour and service ceilings up to 29,000 feet—these tell only part of the story. Really important improvements have been made in facilities for communication, for navigation, and for the Bomber's self-defense. Powered by the new G-Series Wright Cyclone Engines, these new Martin Bombers (Type 9-10-B, Model 159-W) are available for early delivery.

Schools, Services, and Airports

A state-by-state tour of the flying fields

• **ALABAMA**—Oak Airport, south of Foley, is to be improved by the construction of highway facilities and an administration building. A two-plane hangar has already been built. . . . The WPA has allocated about \$35,000 for construction of an airport at Gadsden. Present 1,500 ft. runways will be lengthened to 2,500 ft. . . . David, second and third-place winners in the open landing contest for the Towler trophy at Remount Municipal Airport, were, respectively, Glenn Metzer, Walnut M. Giverson, and Charles W. Johnson. The contest was sponsored by the Birmingham Aero Club.

• **ARIZONA**—The Phoenix Flying Club is co-operating with the WPA on a project to aid the runways at Phoenix Sky Harbor. The Bureau of Aeronautics has approved plans for the work drawn by the city engineering department.

• **ARKANSAS**—Plans are under way for the city of El Dorado to obtain a first-class airport, with the approval of an appropriation by the City Council of \$4,180 with which to purchase two tracts of land. The airport committee of the Chamber of Commerce has guaranteed purchase of a third tract at \$1,100. The action by the City Council is believed to have cleared the way for a WPA project on the field which by \$10,000 will be expanded to complete the east-west runway and provide other improvements.

• **CALIFORNIA**—Carrying out a plan to enlarge the San Francisco Municipal Airport, Mills Field, the supervisors of San Francisco have purchased an additional 132 acres from the Mills Estate at a cost of \$105,000. This gives the airport a total of 1,100 acres. One new 4,000-ft. runway has been completed and two similar runways are under construction. Concrete foundations for the new administration building, to cost \$140,000, have been poured, and the completed structure will be ready about Dec. 15. . . . Sportsman's Aviation Service, run by Al Lutz and John Lintley, has taken over Elmer N. 3 at Los Angeles Municipal Airport. . . . E. R. Carter has been appointed manager of the Santa Monica Municipal Airport in place of V. G. Smith.

• According to a report by Manager W. J. Farman, activities at Long Beach Municipal Airport increased 58 per cent in August over July. The Municipal City Council has raised a proposal to close 2,000 ft. of open ditch, and install a pipe drainage system at the municipal airport. Dedication of the field is scheduled for Nov. 1, when an air show will be staged.

• **COLORADO**—150 men have started work on the Colorado Springs Municipal Airport. A new north-south runway, 4,500 ft. long and 350 ft. wide will be constructed. It will have an alid surface.

• **CONNECTICUT**—The Remount Flying Club has appointed Al J. Ste-

ham chief pilot. It has been announced by James Malachuk, manager of the club. The club will have its headquarters at Milltown Airport. . . . Jack Tward, manager of the New Haven Municipal Airport, was planning an air show for Oct. 13.

• **DELAWARE**—The Noley Business, an organization of aviation enthusiasts and pilots, was planning the first annual Delaware air tour for early September.

• **DISTRICT OF COLUMBIA**—A \$100,000 improvement program under way at Washington Airport will provide a 4,000 ft. paved main runway and a 3,000-ft. cross-runway. Preparations are being made for the future installation of flash type runway lights. 5,000 ft. of drainage tile has been laid. The main runway will cross Military Road on a 64, with a 350 ft. shoulder on each side to ease the grade for automobiles using the road. Shoulders for the rest of the runway will be 200 ft. wide.

• **FLORIDA**—A WPA project employing 150 men is under way at Miami Municipal Airport, putting the field in shape for the South American Air America Air Menoments scheduled for Dec. 10, 11, and 12. Approximately 24 miles of gravel runways are under construction. An additional 3,000 gravelled miles together with a new steel and concrete control tower for towers, piers, and offices of the coast are included in the improvement program. A total of \$4,500 in prize money has been set

THE DAWN PATROL

Here up preparatory to the take-off of the Dawn Patrol of American Legion. John B. Stone, the school's director, reports one of the best scenes in years, with guests actually up in participation here.

Airplane Design

Volume I

PERFORMANCE

by Edward P. Warner

Lately Professor of Aeronautics Engineering,
the Massachusetts Institute of Technology,
and his book is the first in a series of three
covering airplane design.

Second Edition, fully revised
and enlarged by 100 pages
500 pages, 8 x 10, 400 illustrations, \$10.00

Here is the first volume of a thoroughly
revised and enlarged treatise of the
author's earlier work, "Airplane Design."
This book, written by the author, covers
the entire field of airplane design, from
the basic principles of aerodynamics to
the latest developments in airplane
design. It is a complete guide to the
design of airplanes, from the basic
principles of aerodynamics to the latest
developments in airplane design.

For AIRCRAFT CONTROLS

A quarter-century of pioneer experience
is represented in the PRECISION Control
Bearings pictured here. Throughout that
period, NORMA-HOFFMANN Bearings
have been an important factor in aircraft
construction, and have been identified
with practically all of the history-making
achievements in distance, speed, and
endurance flights.

NORMA-HOFFMANN engineers have de-
veloped many of the distinctive bearing
types now accepted standards in aviation
practice. And NORMA-HOFFMANN PRE-
CISION Bearings are today used by per-
centually all representative builders in any
vital applications in aircraft and equipment.

THE PRECISION line of 508 designs which
includes—ball, roller, and tapered roller
bearings—also adapted for practically every
aviation requirement, in planes, engines
and accessories. Write for the Catalog and
request Aircraft Bearing Bulletin. Let our
experts work with you.

NORMA-HOFFMANN BEARINGS CO. INC.

NORMA-HOFFMANN
PRECISION BEARINGS
BALL, ROLLER AND THRUST

ends for the racing events during the
week. Miami will be the scene of
the 1951 convention of the National
Association of State Aviation Officials.
President Roosevelt has been
given a \$7,000 WPA project for the
improvement of Jacksonville airport.
Jacksonville will contribute
\$30,000 in sponsored charges. Nearly
\$125,000 has already been spent by
various government agencies in improv-
ing the field. Plans under the pending
project include surfacing of runways,
grading, and moving hangars farther
from the runways.

• **GEORGIA**—Thirty six planes took
part in the three-day Georgia air tour
last September. Operating prin-
ciples at the Savannah Municipal Air-
port have been issued to Harry G.
Strachan, Jr., by the Savannah City
Council.

• **IDAHO**—Plans in remodeling con-
struction proceedings to serve 300
acres of property for a new airport.
Plans call for a main runway
7,000 ft. long running northwest-south-
east, an east-west runway 7,000 ft.
long, and a third runway 3,000 ft.
long. They would be 300, 600
and 500 ft. wide respectively. The
present municipal airport will be
abandoned. WPA assistance will be
sought for the development of the new field.

• **ILLINOIS**—The East St. Louis
Division of Commerce Aviation Com-
mission is considering the suitability of
the city's purchasing Carle Airport.
The WPA has started a project
to improve Carle's municipal airport.
Plans call for reinforcing taxi run-
ways with cement-bound macadam, and
the construction of two taxiways and
surface taxiways. The Evanston
Flying Club has contributed a hangar on
the Morgan farm, north of Galva.

• **INDIANA**—Buckingham is consider-
ing purchase of the Richmond Airport
property. Five new members have
been added to the St. Joseph Valley
Aviation Club, South Bend. They are
Mrs. Carl Fahren, Mrs. Clifford M.
Wagner, Glenn W. Tschel, Basil C.
Toll and Victor H. Cook. The club is
planning purchase of a new plane.
The South Bend Flying Club was
planning an air show at Bend's Man-
gum Airport South Bend, late in Sep-
tember.

• **MICHIGAN**—A night shift of
WPA workers is in operation at Be-
njamin Church's \$35,000 runway widening
project. The work was scheduled
for completion by late September.

The WPA will contract a
2,000-cu-ft. asphalt loading strip on
the runway at Saginaw Airport. The
strip will be 100 ft. in diameter and
will be constructed at a cost of \$100,000.
The plan is a 400-ft. taxi strip.

The New Haven City Council is
considering establishment of an avia-

tion department to operate Barden Har-
bor Airport. Ben Barden, assistant
manager of the field, has been proposed
for appointment to manager.
The WPA will start construction of
O'Dell and Art Davis, who held at
Bishop Airport, Flint, Mich. in Sep-
tember. About 10,000 spectators at-
tended the event.

• **KENTUCKY**—According to an
announcement by Albert H. New, man-
ager of Bowman Field, Louisville, the
\$30,000 WPA administration building
will be completed about Dec. 1. It will
be a large, single-story building for
construction of concrete runways.

The six members of the Louisville and
Jefferson County Air Board have been
appointed by Mayor William H. Sayer.
They are William H. Sayer, chairman, Louis
Northrup, Albert H. New, W. S.
Kavanaugh, David H. Heston, Jr., and
L. S. Sayer.

• **MAINE**—Wesley A. Marden, land-
ing manager at Bangor, has been ap-
pointed distributor for Taylor Cobs in
Maine. The Bangor City Council
has passed an ordinance providing
for a new runway 3,000 ft. long and
100 ft. wide. The runway will be
located 2 miles west of the Bangor air-
port, and will be located on a 100-acre
tract.

Construction of a WPA
hangar at the Lawrence Airport air-
port was scheduled to start late in Sep-
tember.

• **MISSISSIPPI**—The Memphis Flying
Service, Inc., owned by G. Robert Ford
and H. T. Davis, has signed a five-
year lease on the land now occupied by
its hangar at the Memphis City Airport.
Due to increased business the service
is planning to purchase new planes.
Plans call for a new hangar.

• **MASSACHUSETTS**—The Wren-
tham City Council has passed an ordi-
nance creating a board of three officials
for the management of Barga Airport.
This is a result of action taken
by the Mayor after this city
acquired \$50,000 from the WPA for
extensive improvements. An
airfield, a runway, a taxiway, a WPA
office, and other buildings have been
built on the site. The WPA is planning
to build a new runway at Barga.

• **MICHIGAN**—A night shift of
WPA workers is in operation at Be-
njamin Church's \$35,000 runway widening
project. The work was scheduled
for completion by late September.

The WPA will contract a
2,000-cu-ft. asphalt loading strip on
the runway at Saginaw Airport. The
strip will be 100 ft. in diameter and
will be constructed at a cost of \$100,000.
The plan is a 400-ft. taxi strip.

The New Haven City Council is
considering establishment of an avia-

tion department to operate Barden Har-
bor Airport. Ben Barden, assistant
manager of the field, has been proposed
for appointment to manager.
The WPA will start construction of
O'Dell and Art Davis, who held at
Bishop Airport, Flint, Mich. in Sep-
tember. About 10,000 spectators at-
tended the event.

• **KENTUCKY**—According to an
announcement by Albert H. New, man-
ager of Bowman Field, Louisville, the
\$30,000 WPA administration building
will be completed about Dec. 1. It will
be a large, single-story building for
construction of concrete runways.

The six members of the Louisville and
Jefferson County Air Board have been
appointed by Mayor William H. Sayer.
They are William H. Sayer, chairman, Louis
Northrup, Albert H. New, W. S.
Kavanaugh, David H. Heston, Jr., and
L. S. Sayer.

• **MAINE**—Wesley A. Marden, land-
ing manager at Bangor, has been ap-
pointed distributor for Taylor Cobs in
Maine. The Bangor City Council
has passed an ordinance providing
for a new runway 3,000 ft. long and
100 ft. wide. The runway will be
located 2 miles west of the Bangor air-
port, and will be located on a 100-acre
tract.

Construction of a WPA
hangar at the Lawrence Airport air-
port was scheduled to start late in Sep-
tember.

• **MISSISSIPPI**—The Memphis Flying
Service, Inc., owned by G. Robert Ford
and H. T. Davis, has signed a five-
year lease on the land now occupied by
its hangar at the Memphis City Airport.
Due to increased business the service
is planning to purchase new planes.
Plans call for a new hangar.

TIMKEN- EQUIPPED WHEELS

ASSURE ACCURATE GROUND CONTROL

How modern airplane landing wheel using Timken bearing performs.

Wobbly airplane landing wheels and all of the hazards with which they were associated have long been things of the past. Modern planes of all types and sizes—from the largest to the smallest—handle with the ease and accuracy of modern automobiles when taking off and landing—thanks to the universal adoption of Timken Bearing Equipped wheels.

The modern Timken-equipped airplane wheel is a precision unit in every respect—smooth operating, rigid and scientifically lubricated. It can be relied on for years of efficient service with minimum attention and maintenance.

It will pay you to make sure that your new planes have Timken-equipped landing and tail wheels.

THE TIMKEN ROLLER BEARING COMPANY, CANTON, OHIO

TIMKEN TAPERED ROLLER BEARINGS

those. A four-day program was planned.

... The Arkansas Chamber of Commerce airport committee has decided to withdraw its proposal that English Field be chosen for the city for development of the municipal airport, and has transferred its efforts to the old municipal airport. ... Los Angeles has purchased the hangar and other physical assets at San Diego field, and will move them to a new \$25,000 airport, 6 miles from Hawthorne. The hangar will be enlarged from 60,000 ft. to 120,000 ft. ... St. Paul is considering establishment of a \$500,000 Civilian Air Terminal on the site of the American Airlines airport. WPA assistance will be sought.

•UTAH—The WPA has allotted \$1,000,000 for an airport improvement program at Salt Lake City. Plans call for remodeling of three runways with concrete and asphalt, an addition to the administration building, an apron for the hangar and a field drainage system. City and county officials are planning an aviation week in celebration of the project. Before the money can be obtained, the city must pay up \$240,000.

•VERMONT—The Burlington, Champlain Air Taxi Service, which operates two Lycoming Stearns, has acquired six ships and engines in anticipation of a busy winter season. ... Howard Nelson, manager of the Manchester-Buzz Airport, has just purchased a new Taylor Cab from Weller-Marden of Wrentham, Mass. ... The Evansville board of directors has favored leasing a used ship at the municipal airport to L. E. Menden, manager of the port, for installation of a roof over servicing equipment. ... WPA has allotted \$15,000 for equipment work at the Van Horn Airport.

•VIRGINIA—Staunton is considering establishment of a municipal airport with WPA funds. Staunton airport was opened with a show early in September. The City Council is considering creation of a hangar. ... The WPA has allotted \$20,000 for extending the runway and installing the lighting system at Byrd Airport, Richmond.

•WASHINGTON—Snohomish County Commissioners are planning acquisition of 400 acres of land for construction of a new airport. Present plans call for one runway, to cost \$250,000. ... Seattle councilmen are considering establishment of a hangar near north of Madison Park on Lake Washington. ... Tucson Flying Service, Inc., located at Maricao-Madison Airport, Tucson, is installing short-wave radio equipment at the field.

•WEST VIRGINIA—The first annual Maryland Air Race, sponsored by George DeGrange, was held at Van

Meier field, Martinsburg, early in September. ... Runway surfacing was scheduled to begin at Martinsburg County Airport, CHARLESTON, in September.

Schools

•Using the Boeing trimotored Stearman 80-A transport as a flying classroom, students of the Bureau School of Aeronautics, Oakland (Calif.), taking the transport pilot's course, recently made a flight from Oakland to Chicago and return over United Air Lines' mid-coastline route. The experienced pilot-instructor, Gordon I. Myers, was in charge of the tour, which was to acquaint the students with regular airline operation practices. In the school's radio department, greater stress is being laid on the teaching of radio codes, because of its increasing importance in inter-continental and transoceanic aviation. The instructor is Les Halabowski, senior operator at United Air Lines Oakland station.

•PARKS AIR COLLEGE, PARK ST. LOUIS (Mo.) opened 30 students, representing 12 states, enrolled for the fall term. This brought total enrollment to 302.

•The STARNES SCHOOL of Aeronautics, Tulsa (Okla.), reports that recent enrollments are far ahead of the last few years and most of the new students are enrolling in the longer and more complete transport course. At the same time graduates are being placed in the Sparta factory as soon as they finish their training. In the past few weeks one have gone to work there on the all-metal Sparta Executive model.

•A number of students in the WARREN School of Aeronautics, Los Angeles (Calif.) were chosen for field service at National Air Races in Los Angeles.

•The WHITNEY SCHOOL of Aeronautics has arranged to give a series of lectures on unusual navigation methods at the Florida Flyers' Club, New York, on Tuesday nights through the winter.

•Chief Instructor at the North Texas Agricultural College aviation course is Fred L. Stansby. The school has five open radial engines and five biplane model engines for instruction work. As present students are completing a J-5 Stearman. ... Andrew J. Hesse has been appointed flying instructor for the New London Aviation Club, New London (Conn.). A Taylor Cab is used for instruction. ... A WPA aviation ground school was opened at TAMPA (Fla.) last in September. ... The faculty of the UNIVERSITY of FLORIDA's aviation ground school in Miami consists of David E. Long, William C. Lanning, E. C. Korke and R. J. Chish.

•The JACKSONVILLE, Fla. airport flying school at the Wescott-Gordon airport, Winter Park (Minn.) is planning installation of the equipment on their flying equipment for winter service. A Taylor Cab, a Plett and a Stearns are used in instruction work. ... Howard HICKMAN, flying instructor at the Natick (Mass.) Municipal Airport, has purchased a new Taylor Cab for flying instruction. In addition to the Cab he has a four-engine Stearns. ... Night classes at the BOSTONIAN AVIATION SCHOOL, St. Louis (Mo.) opened Sept. 10.

Aviation People

Who's who and what they are doing

• The Board of Directors of United Aircraft Experts elected as president Thomas F. Hamilton, a director of United Aircraft Corporation and for many years associated with the export activities of the company. He succeeds C. W. Sherrill, a vice-president and director of United Aircraft Corporation, who will devote his full time to the management of the Pratt & Whitney Aircraft Division, a post to which he was appointed last year. J. Ben-Muhammad, former treasurer, was elected vice-president, and James J. O'Brien, who has been in business, A. B. S. Stocker, who was elected vice-president of the Export Corporation last year, continues in that capacity.

Mr. Hamilton, a member of the Early Bird, formed the Hamilton Aero Manufacturing Company in Seattle in 1909, which delivered thousands of propellers to the United States government and its allies during the war. Continuing his propeller production, he developed the first all-metal plane to be landed in America in 1921. In 1929 the Hamilton Standard Propeller Corporation was formed, with Mr. Hamilton serving as chairman of the board of directors and as director of United Aircraft. Later he became president of United Aircraft of California, at that time a United Aircraft subsidiary, then European representative for United Aircraft Export with headquarters abroad, handling foreign sales of Hamilton Standard propellers, Pratt & Whitney engines, and Vought and Stearman planes.

• Goodwill Ambassador Francesco B. Storti, chief of the information section of the Bureau of Air Commerce, has completed a 15,000 mile flight through the West Indies, South America, Central America, Central America, Mexico, and return. On behalf of the government he relied on officials of those countries which had participated in the International Aviation Congress held in Washington last fall, representing appreciation of their cooperation.

• The Netherlands West Indies branch at E.L.M. has as new manager Corneel B. Stuurman, formerly with E.L.M. in Holland. Colonel Stuurman is quartered at Willemstad, Curacao.

• The passenger comfort board more than 3,000 miles of Eastern Air Lines routes sits on the shoulders of Wayne L. Aron, newly made representative of passenger service at present engaged

Thomas F. Hamilton

Charles W. Sherrill

A. Ben-Muhammad

Frederick A. Storti

in a survey of the network. For the past three years he has been with Transcontinental & Western Air, serving as co-pilot, flight dispatcher at Newark and Kansas City, and lately as superintendent of passenger service.

• The new shift for Clarence W. Pease, who will direct the expanded activities of Eastern Air Lines in Indianapolis as district traffic representative for Mayne International, newly placed as co-pilot on Eastern Air Lines Newark to Miami run, for Clark Smith who has been made operator of the new traffic system being installed at Storer Field, for Gen. Clarence L. Trench, who has been transferred to the east and who will be succeeded as Commandant of the 7th Bombardment Group at Hamilton Field, Cal., by Col. Dornheim Jackson, both having been

promoted from the rank of Lieut. Colonel, for Lester C. Lee, A. Wagner, appointed First Wing assistant and air-deputy to Brig. Gen. Dana C. Evers, commander of the First Wing G.I. Air Force at North Field.

• Glasgow's Traveler, Westward, The French Ministry of Pensions, Education has sent Rouven Benveniste to observe American airline operations and technical work, with the expectation of applying his findings in its report of study. During his two months' visit he will drop in at Langley Field, NIT, Culberty, and at the Los Angeles meeting of the S.A.E. Mr. Benveniste was named by General Benveniste in 1932, an act intended to France who is engaged in aeronautical research for Louis in October. . . . General Benveniste, engineer with the Equipment of France, subsidiary of Benveniste Aviation, came to acquaint himself with the present organization. . . . Mr. Benveniste W. E. Davis, who operates Quaker Farm Flying Club at Lympne, England, dropped over for an 8-day visit to try to fly, check, and reports in the vicinity of New York. . . . "Hilberberg" between Aviation P. Benveniste, managing director of Netherlands Steamship Company and Transatlantic A. W. Rive, managing director of International Flight-Bureau Company, an organization of a Dutch airline specialists. . . . Distinguished passenger was Gen. Hens Evers, born in Ghent, leaves place of the airship with the Department of Commerce. The

operator's plan is that the United States built, or have built, a river drifter to put the operator in a profit-making business. . . . also Max Koenig of the German Air Ministry and Gen. Cassinowicz, and President W. Trenchard of the Transatlantic Company, the former being the company's Polish representative.

General L. L. Lohmeyer, a member of the International Convention of the "Hilberberg" Passenger-owners included Gen. L. L. Lohmeyer, Culberty and American Vice of Wright Aeronautical Company, came to read their papers before the meeting of the Lohmeyer Gesellschaft for Luftfahrt Forschung in Berlin. . . . Major Lester D. Gannon, secretary of the Institute of the Aeronautical Sciences, found for the same meeting, in substance by plane to Mission, Tex. in its visit accompanied laboratories in Rome,

AIRWHEEL[®]

-FIRST-CHOICE FOR SAFETY

THERE'S a very simple reason why so many large transports and private aircraft are equipped with Goodyear Airwheels.

Long experience proves that these large, super-soft, shock-absorbing air-cushions are the safest equipment underwheel!

These big rubber "leather-beds" not only protect the whole ship from ground stresses and vibrations in routine landings, but they make safe emergency landings possible on ploughed ground, mud, sand, snow and other hazardous conditions that bog ordinary tires!

That has been proved in countless forced landings that turned out happy landings.

*IF IT ISN'T A GOODYEAR IT ISN'T AN AIRWHEEL

AIRWHEEL is Goodyear's trademark, registered in the U.S.A. and throughout the world, and is used to denote that Goodyear is the exclusive maker of AIRWHEEL Tires.

because Airwheels are big enough and soft enough to spread out and support a heavy ship in soft going.

As the last word, equip with quick-stopping Goodyear Airplane Brakes, too — either hy-

draulic or pneumatic — and you have the perfect safety combination. For full engineering data, write Goodyear, Akron, Ohio, or Los Angeles, California.

Electric resistance welded aircraft fuel tank.
Made of Alcoa Aluminum Alloys.

Alcoa Aluminum Alloys are providing light, safe, economical and efficient aircraft fuel and oil tanks. Since both the materials and methods of construction are important factors, Alcoa Engineers have collaborated with the Aircraft Industries in the development of these tanks.

Constant research has developed important alloys, and extensive practical experience in the most efficient and economical means of joining has been gained by our Joining Division. This experience and the knowledge are available to the industry. Seams may be made by means of gas or electric resistance (spot and seam) welding,

or by riveting or other mechanical means. Electric resistance welded tanks recently constructed by our Joining Division have not only passed the standard 35 hours of vibration testing, but in some instances have exceeded 100 hours.

Although Tanks of Alcoa Aluminum Alloys have met with successful satisfaction, research and development are progressing to make even more dependable tanks for aircraft. If you have specific gas and oil tank problems, why not consult Alcoa Engineers. Address: ALUMINUM COMPANY OF AMERICA, 2112 Gulf Building, Pittsburgh, Pennsylvania.

For Ice Elimination ECLIPSE Mechanical Equipment

ICE formation on aircraft wing and control surfaces, propeller hubs and windshields during winter and high altitude flying leads to obvious dangers. To eliminate ice formation, Eclipse Aviation Corporation, cooperating closely with the B. F. Goodrich Co. of Akron, Ohio (manufacturers of rubber wing and control surface De-Icers) has produced a complete line of mechanical De-Icer and Anti-Icer equipment. With them, ice can be conquered!

In addition to the units illustrated, there are available the following: Dual Motor Distributing Valves • Oil Separators less Relief Valves • Separate Pressure Relief Valves • Check Valves • Suction Regulating Valves • Engine Driven Pumps to provide required suction and air pressure for operation instruments and De-Icer equipment. Full information will be sent on request.

ECLIPSE AVIATION CORPORATION
EAST ORANGE, N. J.

(Subsidiary of Bendix Aviation Corporation)

Above: Eclipse Propeller "Anti-Icer" — Pump (variable output) for application of ice removing fluids to propeller hub slinger and windshields.

Right: Eclipse Remote Control Rheostat (shielded) for propeller "Anti-Icer" pump.

Above: Eclipse Electric Motor Driven De-Icer Distributing Valve (with integral control valve) for operation wing and tail surface Goodrich De-Icers.

Left: Eclipse Electric Motor Driven De-Icer Distributing Valve (less integral control valve) for operation wing and tail surface Goodrich De-Icers.

Right: Eclipse De-Icer Oil Separator with integral regulating valve to control pressure to wing and tail De-Icers.
